Contents

1	The Mark3 Realtime Kernel	1
2	License	3
2.1	License	3
3	Configuring The Mark3 Kernel	5
3.1	Overview	5
3.2	Timer Options	5
3.3	Blocking Objects	6
3.4	Inter-process/thread Communication	7
3.5	Debug Features	7
3.6	Enhancements, Security, Miscellaneous	7
4	Building Mark3	9
4.1	Source Layout	9
4.2	Building the kernel	9
4.3	Building on Windows	11
4.4	Exporting the kernel source	12
5	Getting Started With The Mark3 API	13
5.1	Kernel Setup	13
5.2	Threads	14
5.2.1	Thread Setup	14
5.2.2	Entry Functions	15
5.3	Timers	15
5.4	Semaphores	16
5.5	Mutexes	17
5.6	Event Flags	17
5.7	Messages	18
5.7.1	Message Objects	18
5.7.2	Global Message Pool	19
5.7.3	Message Queues	19
5.7.4	Messaging Example	19

5.8	Mailboxes	20
5.8.1	Mailbox Example	20
5.9	Notification Objects	21
5.9.1	Notification Example	21
5.10	Sleep	21
5.11	Round-Robin Quantum	22
6	Why Mark3?	23
7	When should you use an RTOS?	25
7.1	The reality of system code	25
7.2	Superloops, and their limitations	26
7.2.1	Intro to Superloops	26
7.2.2	The simplest loop	26
7.2.3	Interrupt-Driven Super-loop	27
7.2.4	Cooperative multi-tasking	28
7.2.5	Hybrid cooperative/preemptive multi-tasking	29
7.3	Problems with superloops	30
7.3.1	Hidden Costs	30
7.3.2	Tightly-coupled code	31
7.3.3	No blocking Calls	31
7.3.4	Difficult to guarantee responsiveness	31
7.3.5	Limited preemption capability	31
8	Can you afford an RTOS?	33
8.1	Intro	33
8.2	Application description	34
8.3	Runtime Overhead	35
8.4	Analysis	36
9	Mark3 Design Goals	37
9.1	Overview	37
9.1.1	Services Provided by an RTOS Kernel	37
9.1.2	Guiding Principles of Mark3	37
9.1.3	Be feature competitive	37
9.1.4	Be highly configuration	37
9.1.5	No external dependencies, no new language features	38
9.1.6	Target the most popular hobbyist platforms available	38
9.1.7	Maximize determinism – but be pragmatic	38
9.1.8	Apply engineering principles – and that means discipline, measurement and verification	38
9.1.9	Use Virtualization For Verification	38

10 Mark3 Kernel Architecture	41
10.1 Overview	41
10.2 Threads and Scheduling	43
10.2.1 A Bit About Threads	43
10.2.2 Thread States and ThreadLists	44
10.2.3 Blocking and Unblocking	44
10.2.4 Blocking Objects	45
10.3 Inside the Mark3 Scheduler	46
10.3.1 Considerations for Round-Robin Scheduling	47
10.3.2 Context Switching	47
10.3.3 Putting It All Together	48
10.4 Timers	48
10.4.1 Tick-based Timers	50
10.4.2 Tickless Timers	50
10.4.3 Timer Processing Algorithm	50
10.5 Synchronization and IPC	51
10.6 Blocking Objects	51
10.6.1 Semaphores	52
10.6.2 Mutex	52
10.6.3 Event Flags	52
10.6.4 Notification Objects	52
10.7 Messages and Global Message Queue	53
10.7.1 Messages	53
10.7.2 Message Objects	53
10.7.3 Global Message Pool	53
10.7.4 Message Queues	54
10.7.5 Mailboxes	54
10.7.6 Atomic Operations	54
10.7.7 Drivers	55
10.8 Kernel Proper and Porting	57
11 Build System	65
11.1 Introduction	65
11.2 Mark3 Build Process Overview	66
11.2.1 Pre-Build Phase:	66
11.2.2 Build Phase	67
11.2.3 Test and Profile	67
11.2.4 Release	68
12 Mark3C - C-language API bindings for the Mark3 Kernel.	69
12.1 API Conventions	69

12.2 Allocating Objects	70
12.3 Drivers in Mark3C	70
13 Release Notes	73
13.1 R4 Release	73
13.2 R3 Release	73
13.3 R2	74
13.4 R1 - 2nd Release	74
13.5 R1 - 1st Release	74

Chapter 1

The Mark3 Realtime Kernel

```
--[Mark3 Realtime Platform]-----
```

```

```

The Mark3 Realtime [Kernel](#) is a completely free, open-source, real-time operating system aimed at bringing powerful, easy-to-use multitasking to microcontroller systems without MMUs.

It uses modern programming languages and concepts to minimize code duplication, and its object-oriented design enhances readability. The API is simple – in six function calls, you can set up the kernel, initialize two threads, and start the scheduler.

The source is fully-documented with example code provided to illustrate concepts. The result is a performant RTOS, which is easy to read, easy to understand, and easy to extend to fit your needs.

But Mark3 is bigger than just a real-time kernel, it also contains a number of class-leading features:

- Native implementation in C++, with C-language bindings.
- Device driver HAL which provides a meaningful abstraction around device-specific peripherals.
- Capable recursive-make driven build system which can be used to build all libraries, examples, tests, documentation, and user-projects for any number of targets from the command-line.
- Graphics and UI code designed to simplify the implementation of systems using displays, keypads, joysticks, and touchscreens
- Standards-based custom communications protocol used to simplify the creation of host tools
- A bulletproof, well-documented bootloader for AVR microcontrollers Support for kernel-aware simulators, including Funkenstein's own fIAVR.

Chapter 3

Configuring The Mark3 Kernel

3.1 Overview

The Mark3 [Kernel](#) features a large number of compile-time options that can be set by the user. In this way, the user can build a custom OS kernel that provides only the necessary feature set required by the application, and reduce the code and data requirements of the kernel.

Care has been taken to ensure that all valid combinations of features can be enabled or disabled, barring direct dependencies.

When Mark3 is built, the various compile-time definitions are used to alter how the kernel is compiled, and include or exclude various bits and pieces in order to satisfy the requirements of the selected features. As a result, the kernel must be rebuilt whenever changes are made to the configuration header.

Note that not all demos, libraries, and tests will build successfully if the prerequisite features are not included.

[Kernel](#) options are set by modifying [mark3cfg.h](#), located within the /kernel/public folder.

In the following sections, we will discuss the various configuration options, grouped by functionality.

3.2 Timer Options

KERNEL_USE_TIMERS

This option is related to all kernel time-tracking:

- Timers provide a way for events to be periodically triggered in a lightweight manner. These can be periodic, or one-shot.
- [Thread Quantum](#) (used for round-robin scheduling) is dependent on this module, as is [Thread Sleep](#) functionality.

Setting this option to 0 disables all timer-based functionality within the kernel.

KERNEL_TIMERS_TICKLESS

If you've opted to use the kernel timers module, you have an option as to which timer implementation to use: Tick-based or Tick-less.

Tick-based timers provide a "traditional" RTOS timer implementation based on a fixed-frequency timer interrupt. While this provides very accurate, reliable timing, it also means that the CPU is being interrupted far more often than may be necessary (as not all timer ticks result in "real work" being done).

Tick-less timers still rely on a hardware timer interrupt, but uses a dynamic expiry interval to ensure that the interrupt is only called when the next timer expires. This increases the complexity of the timer interrupt handler, but reduces the number and frequency.

Note that the CPU port ([kerneltimer.cpp](#)) must be implemented for the particular timer variant desired.

Set this option to 1 to use the tickless timer implementation, 0 to use the traditional tick-based approach. Tickless timers are a bit more heavy weight (larger code footprint), but can yield significant power savings as the CPU does not need to wake up at a fixed, high frequency.

KERNEL_USE_TIMEOUTS

By default, if you opt to enable kernel timers, you also get timeout- enabled versions of the blocking object APIs along with it. This support comes at a small cost to code size, but a slightly larger cost to realtime performance - as checking for the use of timers in the underlying internal code costs some cycles.

As a result, the option is given to the user here to manually disable these timeout-based APIs if desired by the user for performance and code-size reasons.

Set this option to 1 to enable timeout-based APIs for blocking calls.

KERNEL_USE_QUANTUM

Do you want to enable time quanta? This is useful when you want to have tasks in the same priority group share time in a controlled way. This allows equal tasks to use unequal amounts of the CPU, which is a great way to set up CPU budgets per thread in a round-robin scheduling system. If enabled, you can specify a number of ticks that serves as the default time period (quantum). Unless otherwise specified, every thread in a priority will get the default quantum.

Set this option to 1 to enable round-robin scheduling.

THREAD_QUANTUM_DEFAULT

This value defines the default thread quantum when `KERNEL_USE_QUANTUM` is enabled. The value defined is a time in milliseconds.

KERNEL_USE_SLEEP

This define enables the [Thread::Sleep\(\)](#) API, which allows a thread to suspend its operation for a defined length of time, specified in ms.

3.3 Blocking Objects

KERNEL_USE_NOTIFY

This is a simple blocking object, where a thread (or threads) are guaranteed to block until an asynchronous event signals the object.

KERNEL_USE_SEMAPHORE

Do you want the ability to use counting/binary semaphores for thread synchronization? Enabling this features provides fully-blocking semaphores and enables all API functions declared in `semaphore.h`. If you have to pick one blocking mechanism, this is the one to choose.

Note that all IPC mechanisms (mailboxes, messages) rely on semaphores, so keep in mind that this is a prerequisite for many other features in the kernel.

KERNEL_USE_MUTEX

Do you want the ability to use mutual exclusion semaphores (mutex) for resource/block protection? Enabling this feature provides mutexes, with priority inheritance, as declared in [mutex.h](#).

KERNEL_USE_EVENTFLAG

Provides additional event-flag based blocking. This relies on an additional per-thread flag-mask to be allocated, which adds 2 bytes to the size of each thread object.

3.4 Inter-process/thread Communication

KERNEL_USE_MESSAGE

Enable inter-thread messaging using message queues. This is the preferred mechanism for IPC for serious multi-threaded communications; generally anywhere a semaphore or event-flag is insufficient.

GLOBAL_MESSAGE_POOL_SIZE

If Messages are enabled, define the size of the default kernel message pool. Messages can be manually added to the message pool, but this mechanism is more convenient and automatic. All message queues can share their message objects from this global pool to maximize efficiency and simplify data management.

KERNEL_USE_MAILBOX

Enable inter-thread messaging using mailboxes. A mailbox manages a blob of data provided by the user, that is partitioned into fixed-size blocks called envelopes. The size of an envelope is set by the user when the mailbox is initialized. Any number of threads can read-from and write-to the mailbox. Envelopes can be sent-to or received-from the mailbox at the head or tail. In this way, mailboxes essentially act as a circular buffer that can be used as a blocking FIFO or LIFO queue.

3.5 Debug Features

KERNEL_USE_THREADNAME

Provide [Thread](#) method to allow the user to set a name for each thread in the system. Adds a const char* pointer to the size of the thread object.

KERNEL_USE_DEBUG

Provides extra logic for kernel debugging, and instruments the kernel with extra asserts, and kernel trace functionality.

KERNEL_ENABLE_LOGGING

Set this to 1 to enable very chatty kernel logging. Since most important things in the kernel emit logs, a large log-buffer and fast output are required in order to keep up. This is a pretty advanced power-user type feature, so it's disabled by default.

KERNEL_ENABLE_USER_LOGGING

This enables a set of logging macros similar to the kernel-logging macros; however, these can be enabled or disabled independently. This allows for user-code to benefit from the built-in kernel logging macros without having to account for the super-high-volume of logs generated by kernel code.

3.6 Enhancements, Security, Miscellaneous

KERNEL_USE_DRIVER

Enabling device drivers provides a posix-like filesystem interface for peripheral device drivers.

KERNEL_USE_DYNAMIC_THREADS

Provide extra [Thread](#) methods to allow the application to create (and more importantly destroy) threads at runtime. useful for designs implementing worker threads, or threads that can be restarted after encountering error conditions.

KERNEL_USE_PROFILER

Provides extra classes for profiling the performance of code. useful for debugging and development, but uses an additional hardware timer.

KERNEL_USE_ATOMIC

Provides support for atomic operations, including addition, subtraction, set, and test-and-set. Add/Sub/Set contain 8, 16, and 32-bit variants.

SAFE_UNLINK

"Safe unlinking" performs extra checks on data to make sure that there are no inconsistencies when performing operations on linked lists. This goes beyond pointer checks, adding a layer of structural and metadata validation to help detect system corruption early.

KERNEL_AWARE_SIMULATION

Include support for kernel-aware simulation. Enabling this feature adds advanced profiling, trace, and environment-aware debugging and diagnostic functionality when Mark3-based applications are run on the fI AVR simulator.

KERNEL_USE_IDLE_FUNC

Enabling this feature removes the necessity for the user to dedicate a complete thread for idle functionality. This saves a full thread stack, but also requires a bit extra static data. This also adds a slight overhead to the context switch and scheduler, as a special case has to be taken into account.

KERNEL_USE_AUTO_ALLOC

This feature enables an additional set of APIs that allow for objects to be created on-the-fly out of a special heap, without having to explicitly allocate them (from stack, heap, or static memory). Note that auto-alloc memory cannot be reclaimed.

AUTO_ALLOC_SIZE

Size (in bytes) of the static pool of memory reserved from RAM for use by the auto allocator (if enabled).

Chapter 4

Building Mark3

Mark3 is distributed with a recursive makefile build system, allowing the entire source tree to be built into a series of libraries with simple make commands.

The way the scripts work, every directory with a valid makefile is scanned, as well as all of its subdirectories. The build then generates binary components for all of the components it finds -libraries and executables. All libraries that are generated can then be imported into an application using the linker without having to copy-and-paste files on a module-by-module basis. Applications built during this process can then be loaded onto a device directly, without requiring a GUI-based IDE. As a result, Mark3 integrates well with 3rd party tools for continuous-integration and automated testing.

This modular framework allows for large volumes of libraries and binaries to be built at once - the default build script leverages this to build all of the examples and unit tests at once, linking against the pre-built kernel, services, and drivers. Whatever can be built as a library is built as a library, promoting reuse throughout the platform, and enabling Mark3 to be used as a platform, with an ecosystem of libraries, services, drivers and applications.

4.1 Source Layout

One key aspect of Mark3 is that system features are organized into their own separate modules. These modules are further grouped together into folders based on the type of features represented:

Root	Base folder, contains recursive makefiles for build system
arduino	Arduino-specific headers and API documentation files
bootloader	Mark3 Bootloader code for AVR microcontrollers
build	Makefiles and device-configuration data for various platforms
docs	Documentation (including this)
drivers	Device driver code for various supported devices
example	Example applications
export	Platform specific output folder, used when running export.sh
fonts	Bitmap fonts converted from TTF, used by Mark3 graphics library
kernel	Basic Mark3 Components (the focus of this manual)
cpu	CPU-specific porting code
scripts	Scripts used to simplify build, documentation, and profiling
libs	Utility code and services, extended system features
stage	Staging directory, where the build system places artifacts
tests	Unit tests, written as C/C++ applications
util	.net-based font converter, terminal, programmer, config util

4.2 Building the kernel

There are 3 main components of the recursive makefile system used to build Mark3 and its associated middleware libraries and examples. The components are the files "base.mak", "platform.mak", and "build.mak"

The base.mak file determines how the kernel, drivers, and libraries are built, for what targets, and with what options. These options are set as variables that are included in a "platform.mak" file for your target, located under the /builds

directory. "platform.mak" is included for all build steps, and is the place where all chip/board-specific toolchain configuration takes place.

Build.mak contains the base logic which is used to perform a recursive make in all project directories. Unless you really know what you're doing, it's best to leave this as-is.

Beyond the essential makefiles, the build system uses a series of environment variables to configure a recursive make-based build system appropriately for a given target part and toolchain.

Below is an overview of the main variables used to configure the build.

```

STAGE      - Location in the filesystem where the build output is stored
ROOT_DIR   - The location of the root source tree
ARCH       - The CPU architecture to build against
VARIANT    - The variant of the above CPU to target
TOOLCHAIN  - Which toolchain to build with (dependent on ARCH and VARIANT)

```

You must make sure that all required toolchain paths are set in your system environment variables so that they are accessible directly through from the command-line

Once a sane environment has been created, the kernel, libraries, examples and tests can be built by running `./scripts/build.sh` from the root directory. By default, Mark3 builds for the atmega328p target, but the target can be selected by manually configuring the above environment variables, or by running the included `./scripts/set_target.sh` script as follows:

```
. ./scripts/set_target.sh <architecture> <variant> <toolchain>
```

Where:

```

<architecture> is the target CPU architecture(i.e. avr, msp430, cm0, cm3, cm4f)
<variant>      is the part name (i.e. atmega328p, msp430f2274, generic)
<toolchain>    is the build toolchain (i.e. gcc)

```

Once configured, you can build the source tree using the various make targets:

- make headers
 - copy all headers in each module's /public subdirectory to the location specified by STAGE environment variable's ./inc subdirectory.
- make library
 - regenerate all objects copy marked as libraries (i.e. the kernel + drivers). Resulting binaries are copied into STAGE's ./lib subdirectory.
- make binary
 - build all executable projects in the root directory structure. In the default distribution, this includes the basic set of demos.

These steps are chained together automatically as part of the build.sh script found under the /scripts subdirectory. Running `./scripts/build.sh` from the root of the embedded source directory will result in all headers being exported, libraries built, and applications built. This script will also default to building for atmega328p using GCC if none of the required environment variables have previously been configured.

To add new components to the recursive build system, simply add your code into a new folder beneath the root install location.

Source files, the module makefile and private header files go directly in the new folder, while public headers are placed in a ./public subdirectory. Create a ./obj directory to hold the output from the builds.

The contents of the module makefile looks something like this:

```
# Include common prelude make file
include $(ROOT_DIR)base.mak

# If we're building a library, set IS_LIB and LIBNAME
# If we're building an app, set IS_APP and APPNAME
IS_LIB=1
LIBNAME=mylib

#this is the list of the source modules required to build the kernel
CPP_SOURCE = mylib.cpp \
             someotherfile.cpp

# Similarly, C-language source would be under the C_SOURCE variable.

# Include the rest of the script that is actually used for building the
# outputs
include $(ROOT_DIR)build.mak
```

Once you've placed your code files in the right place, and configured the makefile appropriately, call the following sequence to guarantee that your code will be built.

```
> make headers
> make library
> make binary
```

Note that library or app-specific environment variables can be set (or modified from the defaults) from within the body of the makefile. For example, the CFLAGS, CPPFLAGS, and LFLAGS variables can be used to supply additional chip-specific toolchain flags. The flags can be used to allow a user to reference chip-specific startup code, headers, middleware, or linker scripts that aren't part of the standard Mark3 distribution.

4.3 Building on Windows

Building Mark3 on Windows is the same as on Linux, but there are a few prerequisites that need to be taken into consideration before the build scripts and makefiles will work as expected.

Below is an example of setting up the AVR toolchain on Windows:

Step 1 - Install Latest Atmel Studio IDE

Atmel Studio contains the AVR8 GCC toolchain, which contains the necessary compilers, assemblers, and platform support required to turn the source modules into libraries and executables.

To get Atmel Studio, go to the Atmel website (<http://www.atmel.com>) and register to download the latest version. This is a free download (and rather large). The included IDE (if you choose to use it) is very slick, as it's based on Visual Studio, and contains a wonderful cycle-accurate simulator for AVR devices. In fact, the simulator is so good that most of the kernel and its drivers were developed using this tool.

Once you have downloaded and installed Atmel Studio, you will need to add the location of the AVR toolchain to the PATH environment variable.

To do this, go to Control Panel -> System and Security -> System -> Advanced System Settings, and edit the PATH variable. Append the location of the toolchain bin folder to the end of the variable.

On Windows x64, it should look something like this:

```
C:\Program Files (x86)\Atmel\Atmel Toolchain\AVR8 GCC\Native\3.4.2.1002\avr8-gnu-toolchain\bin
```

Step 2 - Install MinGW and MinSys

MinGW (and MinSys in particular) provide a unix-like environment that runs under windows. Some of the utilities provided include a version of the bash shell, and GNU standard make - both which are required by the Mark3 recursive build system.

The MinGW installer can be downloaded from its project page on SourceForge. When installing, be sure to select the "MinSys" component.

Once installed, add the MinSys binary path to the PATH environment variable, in a similar fashion as with Atmel Studio in Step 1.

Step 3 - Setup Include Paths in Platform Makefile

The AVR header file path must be added to the "platform.mak" makefile for each AVR Target you are attempting to build for. These files can be located under /embedded/build/avr/atmegaXXX/. The path to the includes directory should be added to the end of the CFLAGS and CPPFLAGS variables, as shown in the following:

```
TEST_INC="/c/Program Files (x86)/Atmel/Atmel Toolchain/AVR8
GCC/Native/3.4.2.1002/avr8-gnu-toolchain/include"
CFLAGS += -I$(TEST_INC)
CPPFLAGS += -I$(TEST_INC)
```

Step 4 - Build Mark3 using Bash

Launch a terminal to your Mark3 base directory, and cd into the "embedded" folder. You should now be able to build Mark3 by running "bash ./build.sh" from the command-line.

Alternately, you can run bash itself, building Mark3 by running ./build.sh or the various make targets using the same syntax as documented previously.

Note - building on Windows is *slow*. This has a lot to do with how "make" performs under windows. There are faster substitutes for make (such as cs-make) that are exponentially quicker, and approach the performance of make on Linux. Other mechanisms, such as running make with multiple concurrent jobs (i.e. "make -j4") also helps significantly, especially on systems with multicore CPUs.

4.4 Exporting the kernel source

While the build system is flexible enough to adapt to any toolchain, it may be desirable to integrate the Mark3 kernel and associated drivers/libraries into another build system.

Mark3 provides a script (the aptly-named export.sh) which allow for the source for any supported port to be exported for this purpose. This script will also generate appropriate doxygen documentation, and package the whole of it together in a zip file. The files in the archive are placed in a "flat" heirarchy, and do not require any specific path structure to be maintained when imported into another build system.

As a special feature, if the "arduino" AVR target is specified, additional pre-processing is done on the source to turn the standard Mark3 kernel into a library that can be imported directly into Arudino IDE. This is also how the official Mark3 arduino-compatible releases are generated (hosted on mark3os.com and sourceforge.net)

To exercise the build system, type the following from the main mark3 embedded source directory:

```
> ./scripts/export.sh <target>
```

Where:

Target is one of the following:

```
atmega328p
atmega644
atmega1280
atmega2560
atmega1284p
atxmega256a3
arduino
arduino2560
samd20
cortex_m0
cortex_m3
cortex_m4f
msp430f2274
```

If successful, the generated artifacts will be placed in an output folder under the ./export directory.

Additionally, if doxygen is found on the host system's PATH, a copy of the manual (using the specific port's source code) will be generated and archived with the source release. If pdflatex is also found on the host's PATH, a PDF copy of the manual will be generated, tailored to the selected target.

Chapter 5

Getting Started With The Mark3 API

5.1 Kernel Setup

This section details the process of defining threads, initializing the kernel, and adding threads to the scheduler.

If you're at all familiar with real-time operating systems, then these setup and initialization steps should be familiar. I've tried very hard to ensure that as much of the heavy lifting is hidden from the user, so that only the bare minimum of calls are required to get things started.

The examples presented in this chapter are real, working examples taken from the ATmega328p port.

First, you'll need to create the necessary data structures and functions for the threads:

1. Create a [Thread](#) object for all of the "root" or "initial" tasks.
2. Allocate stacks for each of the Threads
3. Define an entry-point function for each [Thread](#)

This is shown in the example code below:

```
//-----
#include "thread.h"
#include "kernel.h"

//1) Create a thread object for all of the "root" or "initial" tasks
static Thread AppThread;
static Thread IdleThread;

//2) Allocate stacks for each thread
#define STACK_SIZE_APP      (192)
#define STACK_SIZE_IDLE     (128)

static uint8_t aucAppStack[STACK_SIZE_APP];
static uint8_t aucIdleStack[STACK_SIZE_IDLE];

//3) Define entry point functions for each thread
void AppThread(void);
void IdleThread(void);
```

Next, we'll need to add the required kernel initialization code to main. This consists of running the [Kernel's](#) init routine, initializing all of the threads we defined, adding the threads to the scheduler, and finally calling [Kernel::Start\(\)](#), which transfers control of the system to the RTOS.

These steps are illustrated in the following example.

```
int main(void)
{
    //1) Initialize the kernel prior to use
    Kernel::Init();           // MUST be before other kernel ops

    //2) Initialize all of the threads we've defined
```

```

AppThread.Init( aucAppStack,      // Pointer to the stack
                STACK_SIZE_APP,   // Size of the stack
                1,                // Thread priority
                (void*)AppEntry,   // Entry function
                NULL );           // Entry function argument

IdleThread.Init( aucIdleStack,    // Pointer to the stack
                 STACK_SIZE_IDLE, // Size of the stack
                 0,               // Thread priority
                 (void*)IdleEntry, // Entry function
                 NULL );          // Entry function argument

//3) Add the threads to the scheduler
AppThread.Start();           // Actively schedule the threads
IdleThread.Start();

//4) Give control of the system to the kernel
Kernel::Start();             // Start the kernel!
}

```

Not much to it, is there? There are a few noteworthy points in this code, though.

In order for the kernel to work properly, a system must always contain an idle thread; that is, a thread at priority level 0 that never blocks. This thread is responsible for performing any of the low-level power management on the CPU in order to maximize battery life in an embedded device. The idle thread must also never block, and it must never exit. Either of these operations will cause undefined behavior in the system.

The App thread is at a priority level greater-than 0. This ensures that as long as the App thread has something useful to do, it will be given control of the CPU. In this case, if the app thread blocks, control will be given back to the Idle thread, which will put the CPU into a power-saving mode until an interrupt occurs.

Stack sizes must be large enough to accommodate not only the requirements of the threads, but also the requirements of interrupts - up to the maximum interrupt-nesting level used. Stack overflows are super-easy to run into in an embedded system; if you encounter strange and unexplained behavior in your code, chances are good that one of your threads is blowing its stack.

5.2 Threads

Mark3 Threads act as independent tasks in the system. While they share the same address-space, global data, device-drivers, and system peripherals, each thread has its own set of CPU registers and stack, collectively known as the thread's **context**. The context is what allows the RTOS kernel to rapidly switch between threads at a high rate, giving the illusion that multiple things are happening in a system, when really, only one thread is executing at a time.

5.2.1 Thread Setup

Each instance of the [Thread](#) class represents a thread, its stack, its CPU context, and all of the state and metadata maintained by the kernel. Before a [Thread](#) will be scheduled to run, it must first be initialized with the necessary configuration data.

The Init function gives the user the opportunity to set the stack, stack size, thread priority, entry-point function, entry-function argument, and round-robin time quantum:

[Thread](#) stacks are pointers to blobs of memory (usually char arrays) carved out of the system's address space. Each thread must have a stack defined that's large enough to handle not only the requirements of local variables in the thread's code path, but also the maximum depth of the ISR stack.

Priorities should be chosen carefully such that the shortest tasks with the most strict determinism requirements are executed first - and are thus located in the highest priorities. Tasks that take the longest to execute (and require the least degree of responsiveness) must occupy the lower thread priorities. The idle thread must be the only thread occupying the lowest priority level.

The thread quantum only applies when there are multiple threads in the ready queue at the same priority level. This interval is used to kick-off a timer that will cycle execution between the threads in the priority list so that they each get a fair chance to execute.

The entry function is the function that the kernel calls first when the thread instance is first started. Entry functions have at most one argument - a pointer to a data-object specified by the user during initialization.

An example thread initialization is shown below:

```
Thread clMyThread;
uint8_t aucStack[192];

void AppEntry(void)
{
    while(1)
    {
        // Do something!
    }
}

...
{
    clMyThread.Init(aucStack,    // Pointer to the stack to use by this thread
                    192,        // Size of the stack in bytes
                    1,          // Thread priority (0 = idle, 7 = max)
                    (void*)AppEntry, // Function where the thread starts executing
                    NULL );      // Argument passed into the entry function
}
```

Once a thread has been initialized, it can be added to the scheduler by calling:

```
clMyThread.Start();
```

The thread will be placed into the [Scheduler](#)'s queue at the designated priority, where it will wait its turn for execution.

5.2.2 Entry Functions

Mark3 Threads should not run-to-completion - they should execute as infinite loops that perform a series of tasks, appropriately partitioned to provide the responsiveness characteristics desired in the system.

The most basic [Thread](#) loop is shown below:

```
void Thread( void *param )
{
    while(1)
    {
        // Do Something
    }
}
```

Threads can interact with eachother in the system by means of synchronization objects ([Semaphore](#)), mutual-exclusion objects ([Mutex](#)), Inter-process messaging ([MessageQueue](#)), and timers ([Timer](#)).

Threads can suspend their own execution for a predetermined period of time by using the static [Thread::Sleep\(\)](#) method. Calling this will block the [Thread](#)'s executin until the amount of time specified has ellapsed. Upon expiry, the thread will be placed back into the ready queue for its priority level, where it awaits its next turn to run.

5.3 Timers

[Timer](#) objects are used to trigger callback events periodic or on a one-shot (alarm) basis.

While extremely simple to use, they provide one of the most powerful execution contexts in the system. The timer callbacks execute from within the timer callback ISR in an interrupt-enabled context. As such, timer callbacks are considered higher-priority than any thread in the system, but lower priority than other interrupts. Care must be taken to ensure that timer callbacks execute as quickly as possible to minimize the impact of processing on the throughput of tasks in the system. Wherever possible, heavy-lifting should be deferred to the threads by way of semaphores or messages.

Below is an example showing how to start a periodic system timer which will trigger every second:

```

{
    Timer clTimer;
    clTimer.Init();

    clTimer.Start( 1000,
                  1,
                  MyCallback,
                  (void*)&my_data );

    ... // Keep doing work in the thread
}

// Callback function, executed from the timer-expiry context.
void MyCallback( Thread *pclOwner_, void *pvData_ )
{
    LED.Flash(); // Flash an LED.
}

```

5.4 Semaphores

Semaphores are used to synchronized execution of threads based on the availability (and quantity) of application-specific resources in the system. They are extremely useful for solving producer-consumer problems, and are the method-of-choice for creating efficient, low latency systems, where ISRs post semaphores that are handled from within the context of individual threads. (Yes, Semaphores can be posted - but not pended - from the interrupt context).

The following is an example of the producer-consumer usage of a binary semaphore:

```

Semaphore clSemaphore; // Declare a semaphore shared between a producer and a consumer thread.

void Producer()
{
    clSemaphore.Init(0, 1);
    while(1)
    {
        // Do some work, create something to be consumed

        // Post a semaphore, allowing another thread to consume the data
        clSemaphore.Post();
    }
}

void Consumer()
{
    // Assumes semaphore initialized before use...
    While(1)
    {
        // Wait for new data from the producer thread
        clSemaphore.Pend();

        // Consume the data!
    }
}

```

And an example of using semaphores from the ISR context to perform event- driven processing.

```

Semaphore clSemaphore;

__interrupt__ MyISR()
{
    clSemaphore.Post(); // Post the interrupt. Lightweight when uncontested.
}

void MyThread()
{
    clSemaphore.Init(0, 1); // Ensure this is initialized before the MyISR interrupt is enabled.
    while(1)
    {
        // Wait until we get notification from the interrupt
        clSemaphore.Pend();

        // Interrupt has fired, do the necessary work in this thread's context
        HeavyLifting();
    }
}

```

5.5 Mutexes

Mutexes (Mutual exclusion objects) are provided as a means of creating "protected sections" around a particular resource, allowing for access of these objects to be serialized. Only one thread can hold the mutex at a time - other threads have to wait until the region is released by the owner thread before they can take their turn operating on the protected resource. Note that mutexes can only be owned by threads - they are not available to other contexts (i.e. interrupts). Calling the mutex APIs from an interrupt will cause catastrophic system failures.

Note that these objects are also not recursive- that is, the owner thread can not attempt to claim a mutex more than once.

Priority inheritance is provided with these objects as a means to avoid priority inversions. Whenever a thread at a priority than the mutex owner blocks on a mutex, the priority of the current thread is boosted to the highest-priority waiter to ensure that other tasks at intermediate priorities cannot artificially prevent progress from being made.

Mutex objects are very easy to use, as there are only three operations supported: Initialize, Claim and Release. An example is shown below.

```

Mutex clMutex; // Create a mutex globally.

void Init()
{
    // Initialize the mutex before use.
    clMutex.Init();
}

// Some function called from a thread
void Thread1Function()
{
    clMutex.Claim();

    // Once the mutex is owned, no other thread can
    // enter a block protect by the same mutex

    my_protected_resource.do_something();
    my_protected_resource.do_something_else();

    clMutex.Release();
}

// Some function called from another thread
void Thread2Function()
{
    clMutex.Claim();

    // Once the mutex is owned, no other thread can
    // enter a block protect by the same mutex

    my_protected_resource.do_something();
    my_protected_resource.do_different_things();

    clMutex.Release();
}

```

5.6 Event Flags

Event Flags are another synchronization object, conceptually similar to a semaphore.

Unlike a semaphore, however, the condition on which threads are unblocked is determined by a more complex set of rules. Each Event Flag object contains a 16-bit field, and threads block, waiting for combinations of bits within this field to become set.

A thread can wait on any pattern of bits from this field to be set, and any number of threads can wait on any number of different patterns. Threads can wait on a single bit, multiple bits, or bits from within a subset of bits within the field.

As a result, setting a single value in the flag can result in any number of threads becoming unblocked simultaneously. This mechanism is extremely powerful, allowing for all sorts of complex, yet efficient, thread synchronization schemes that can be created using a single shared object.

Note that Event Flags can be set from interrupts, but you cannot wait on an event flag from within an interrupt.

Examples demonstrating the use of event flags are shown below.

```
// Simple example showing a thread blocking on a multiple bits in the
// fields within an event flag.

EventFlag clEventFlag;

int main()
{
    ...
    clEventFlag.Init(); // Initialize event flag prior to use
    ...
}

void MyInterrupt()
{
    // Some interrupt corresponds to event 0x0020
    clEventFlag.Set(0x0020);
}

void MyThreadFunc()
{
    ...
    while(1)
    {
        ...
        uint16_t ul6WakeCondition;

        // Allow this thread to block on multiple flags
        ul6WakeCondition = clEventFlag.Wait(0x00FF, EVENT_FLAG_ANY);

        // Clear the event condition that caused the thread to wake (in this case,
        // ul6WakeCondition will equal 0x20 when triggered from the interrupt above)
        clEventFlag.Clear(ul6WakeCondition);

        // <do something>
    }
}
```

5.7 Messages

Sending messages between threads is the key means of synchronizing access to data, and the primary mechanism to perform asynchronous data processing operations.

Sending a message consists of the following operations:

- Obtain a [Message](#) object from the global message pool
- Set the message data and event fields
- Send the message to the destination message queue

While receiving a message consists of the following steps:

- Wait for a messages in the destination message queue
- Process the message data
- Return the message back to the global message pool

These operations, and the various data objects involved are discussed in more detail in the following section.

5.7.1 Message Objects

[Message](#) objects are used to communicate arbitrary data between threads in a safe and synchronous way.

The message object consists of an event code field and a data field. The event code is used to provide context to the message object, while the data field (essentially a void * data pointer) is used to provide a payload of data corresponding to the particular event.

Access to these fields is marshalled by accessors - the transmitting thread uses the `SetData()` and `SetCode()` methods to seed the data, while the receiving thread uses the `GetData()` and `GetCode()` methods to retrieve it.

By providing the data as a void data pointer instead of a fixed-size message, we achieve an unprecedented measure of simplicity and flexibility. Data can be either statically or dynamically allocated, and sized appropriately for the event without having to format and reformat data by both sending and receiving threads. The choices here are left to the user - and the kernel doesn't get in the way of efficiency.

It is worth noting that you can send messages to message queues from within ISR context. This helps maintain consistency, since the same APIs can be used to provide event-driven programming facilities throughout the whole of the OS.

5.7.2 Global Message Pool

To maintain efficiency in the messaging system (and to prevent over-allocation of data), a global pool of message objects is provided. The size of this message pool is specified in the implementation, and can be adjusted depending on the requirements of the target application as a compile-time option.

Allocating a message from the message pool is as simple as calling the `GlobalMessagePool::Pop()` Method.

Messages are returned back to the `GlobalMessagePool::Push()` method once the message contents are no longer required.

One must be careful to ensure that discarded messages always are returned to the pool, otherwise a resource leak can occur, which may cripple the operating system's ability to pass data between threads.

5.7.3 Message Queues

`Message` objects specify data with context, but do not specify where the messages will be sent. For this purpose we have a `MessageQueue` object. Sending an object to a message queue involves calling the `MessageQueue::Send()` method, passing in a pointer to the `Message` object as an argument.

When a message is sent to the queue, the first thread blocked on the queue (as a result of calling the `MessageQueue::Receive()` method) will wake up, with a pointer to the `Message` object returned.

It's worth noting that multiple threads can block on the same message queue, providing a means for multiple threads to share work in parallel.

5.7.4 Messaging Example

```
// Message queue object shared between threads
MessageQueue cMsgQ;

// Function that initializes the shared message queue
void MsgQInit()
{
    cMsgQ.Init();
}

// Function called by one thread to send message data to
// another
void TxMessage()
{
    // Get a message, initialize its data
    Message *pClMsg = GlobalMessagePool::Pop();

    pClMsg->SetCode(0xAB);
    pClMsg->SetData((void*)some_data);

    // Send the data to the message queue
    cMsgQ.Send(pClMsg);
}

// Function called in the other thread to block until
// a message is received in the message queue.
void RxMessage()
{
    Message *pClMsg;
```

```

// Block until we have a message in the queue
pclMsg = clMsgQ.Receive();

// Do something with the data once the message is received
pclMsg->GetCode();

// Free the message once we're done with it.
GlobalMessagePool::Push(pclMsg);
}

```

5.8 Mailboxes

Another form of IPC is provided by Mark3, in the form of Mailboxes and Envelopes.

Mailboxes are similar to message queues in that they provide a synchronized interface by which data can be transmitted between threads.

Where [Message](#) Queues rely on linked lists of lightweight message objects (containing only message code and a void* data-pointer), which are inherently abstract, Mailboxes use a dedicated blob of memory, which is carved up into fixed-size chunks called Envelopes (defined by the user), which are sent and received. Unlike message queues, mailbox data is copied to and from the mailboxes dedicated pool.

Mailboxes also differ in that they provide not only a blocking "receive" call, but also a blocking "send" call, providing the opportunity for threads to block on "mailbox full" as well as "mailbox empty" conditions.

All send/receive APIs support an optional timeout parameter if the `KERNEL_USE_TIMEOUTS` option has been configured in [mark3cfg.h](#)

5.8.1 Mailbox Example

```

// Create a mailbox object, and define a buffer that will be used to store the
// mailbox' envelopes.
static Mailbox clMbox;
static uint8_t aucMBoxBuffer[128];

...
void InitMailbox(void)
{
    // Initialize our mailbox, telling it to use our defined buffer for envelope
    // storage. Pass in the size of the buffer, and set the size of each
    // envelope to 16 bytes. This gives u16 a mailbox capacity of (128 / 16) = 8
    // envelopes.
    clMbox.Init((void*)aucMBoxBuffer, 128, 16);
}

...
void SendThread(void)
{
    // Define a buffer that we'll eventually send to the
    // mailbox. Note the size is the same as that of an
    // envelope.
    uint8_t aucTxBuf[16];

    while(1)
    {
        // Copy some data into aucTxBuf, a 16-byte buffer, the
        // same size as a mailbox envelope.
        ...

        // Deliver the envelope (our buffer) into the mailbox
        clMbox.Send((void*)aucTxBuf);
    }
}

...
void RecvThred(void)
{
    uint8_t aucRxBuf[16];

    while(1)
    {
        // Wait until there's a message in our mailbox. Once
        // there is a message, read it into our local buffer.
        cmMbox.Receive((void*)aucRxBuf);
    }
}

```

```

        // Do something with the contents of aucRxBuf, which now
        // contains an envelope of data read from the mailbox.
        ...
    }
}

```

5.9 Notification Objects

Notification objects are the most lightweight of all blocking objects supplied by Mark3.

using this blocking primitive, one or more threads wait for the notification object to be signalled by code elsewhere in the system (i.e. another thread or interrupt). Once the the notification has been signalled, all threads currently blocked on the object become unblocked.

5.9.1 Notification Example

```

static Notify clNotifier;

...
void MyThread(void *unused_)
{
    // Initialize our notification object before use
    clNotifier.Init();

    while (1)
    {
        // Wait until our thread has been notified that it
        // can wake up.
        clNotifier.Wait();

        ...
        // Thread has woken up now -- do something!
    }
}

...
void SignalCallback(void)
{
    // Something in the system (interrupt, thread event, IPC,
    // etc.,) has called this function. As a result, we need
    // our other thread to wake up. Call the Notify object's
    // Signal() method to wake the thread up. Note that this
    // will have no effect if the thread is not presently
    // blocked.

    clNotifier.Signal();
}

```

5.10 Sleep

There are instances where it may be necessary for a thread to poll a resource, or wait a specific amount of time before proceeding to operate on a peripheral or volatile piece of data.

While the [Timer](#) object is generally a better choice for performing time-sensitive operations (and certainly a better choice for periodic operations), the [Thread::Sleep\(\)](#) method provides a convenient (and efficient) mechanism that allows for a thread to suspend its execution for a specified interval.

Note that when a thread is sleeping it is blocked, during which other threads can operate, or the system can enter its idle state.

```

int GetPeripheralData()
{
    int value;
    // The hardware manual for a peripheral specifies that
    // the "foo()" method will result in data being generated
    // that can be captured using the "bar()" method.
    // However, the value only becomes valid after 10ms

    peripheral.foo();
    Thread::Sleep(10); // Wait 10ms for data to become valid
    value = peripheral.bar();
}

```

```
    return value;  
}
```

5.11 Round-Robin Quantum

Threads at the same thread priority are scheduled using a round-robin scheme. Each thread is given a timeslice (which can be configured) of which it shares time amongst ready threads in the group. Once a thread's timeslice has expired, the next thread in the priority group is chosen to run until its quantum has expired - the cycle continues over and over so long as each thread has work to be done.

By default, the round-robin interval is set at 4ms.

This value can be overridden by calling the thread's `SetQuantum()` with a new interval specified in milliseconds.

Chapter 6

Why Mark3?

My first job after graduating from university in 2005 was with a small company that had a very old-school, low-budget philosophy when it came to software development.

Every make-or-buy decision ended with "make" when it came to tools. It was the kind of environment where vendors cost us money, but manpower was free. In retrospect, we didn't have a ton of business during the time that I worked there, and that may have had something to do with the fact that we were constantly short on ready cash for things we could code ourselves.

Early on, I asked why we didn't use industry-standard tools - like JTAG debuggers or IDEs. One senior engineer scoffed that debuggers were tools for wimps - and something that a good programmer should be able to do without. After all - we had serial ports, GPIOs, and a bi-color LED on our boards. Since these were built into the hardware, they didn't cost us a thing. We also had a single software "build" server that took 5 minutes to build a 32k binary on its best days, so when we had to debug code, it was a painful process of trial and error, with lots of Youtube between iterations. We complained that tens of thousands of dollars of productivity was being flushed away that could have been solved by implementing a proper build server - and while we eventually got our wish, it took far more time than it should have.

Needless to say, software development was painful at that company. We made life hard on ourselves purely out of pride, and for the right to say that we walked "up-hills both ways through 3 feet of snow, everyday". Our code was tied ever-so-tightly to our hardware platform, and the system code was indistinguishable from the application. While we didn't use an RTOS, we had effectively implemented a 3-priority threading scheme using a carefully designed interrupt nesting scheme with event flags and a while(1) superloop running as a background thread. Nothing was abstracted, and the code was always optimized for the platform, presumably in an effort to save on code size and wasted cycles. I asked why we didn't use an RTOS in any of our systems and received dismissive scoffs - the overhead from thread switching and maintaining multiple threads could not be tolerated in our systems according to our chief engineers. In retrospect, our ad-hoc system was likely as large as my smallest kernel, and had just as much context switching (although it was hidden by the compiler).

And every time a new iteration of our product was developed, the firmware took far too long to bring up, because the algorithms and data structures had to be re-tooled to work with the peripherals and sensors attached to the new boards. We worked very hard in an attempt to reinvent the wheel, all in the name of producing "efficient" code.

Regardless, I learned a lot about embedded software development.

Most important, I learned that good design is the key to good software; and good design doesn't have to come at a price. In all but the smallest of projects, the well-designed, well-abstracted code is not only more portable, but it's usually smaller, easier to read, and easier to reuse.

Also, since we had all the time in the world to invest in developing our own tools, I gained a lot of experience building them, and making use of good, free PC tools that could be used to develop and debug a large portion of our code. I ended up writing PC-based device and peripheral simulators, state-machine frameworks, and abstractions for our horrible ad-hoc system code. At the end of the day, I had developed enough tools that I could solve a lot of our development problems without having to re-inventing the wheel at each turn. Gaining a background in how these tools worked gave me a better understanding of how to use them - making me more productive at the jobs that I've had since.

I am convinced that designing good software takes honest effort up-front, and that good application code cannot be written unless it is based on a solid framework. Just as the wise man builds his house on rocks, and not on sand, wise developers write applications based on a well-defined platforms. And while you can probably build a house using nothing but a hammer and sheer will, you can certainly build one a lot faster with all the right tools.

This conviction lead me to development my first RTOS kernel in 2009 - FunkOS. It is a small, yet surprisingly full-featured kernel. It has all the basics (semaphores, mutexes, round-robin and preemptive scheduling), and some pretty advanced features as well (device drivers and other middleware). However, it had two major problems - it doesn't scale well, and it doesn't support many devices.

While I had modest success with this kernel (it has been featured on some blogs, and still gets around 125 downloads a month), it was nothing like the success of other RTOS kernels like uC/OS-II and FreeRTOS. To be honest, as a one-man show, I just don't have the resources to support all of the devices, toolchains, and evaluation boards that a real vendor can. I had never expected my kernel to compete with the likes of them, and I don't expect Mark3 to change the embedded landscape either.

My main goal with Mark3 was to solve the technical shortfalls in the FunkOS kernel by applying my experience in kernel development. As a result, Mark3 is better than FunkOS in almost every way; it scales better, has lower interrupt latency, and is generally more thoughtfully designed (all at a small cost to code size).

Another goal I had was to create something easy to understand, that could be documented and serve as a good introduction to RTOS kernel design. The end result of these goals is the kernel as presented in this book - a full source listing of a working OS kernel, with each module completely documented and explained in detail.

Finally, I wanted to prove that a kernel written entirely in C++ could perform just as well as one written in C. Mark3 is fully benchmarked and profiled – you can see exactly how much it costs to call certain APIs or include various features in the kernel.

And in addition, the code is more readable and easier to understand as a result of making use of object-oriented concepts provided by C++. Applications are easier to write because common concepts are encapsulated into objects (Threads, Semaphores, Mutexes, etc.) with their own methods and data, as opposed to APIs which rely on lots of explicit pointer or handle-passing, type casting, and other operations that are typically considered "unsafe" or "advanced" topics in C.

Chapter 7

When should you use an RTOS?

7.1 The reality of system code

System code can be defined as the program logic required to manage, synchronize, and schedule all of the resources (CPU time, memory, peripherals, etc.) used by the application running on the CPU. And it's true that a significant portion of the code running on an embedded system will be system code. No matter how simple a system is, whether or not this logic is embedded directly into the application (bare-metal system), or included as part of a well-defined stack on which an application is written (RTOS-based); system code is still present, and it comes with a cost.

As an embedded systems is being designed, engineers have to decide which approach to take: Bare-metal, or RTOS. There are advantages and disadvantages to each – and a reasonable engineer should always perform a thorough analysis of the pros and cons of each - in the context of the given application - before choosing a path.

The following figure demonstrates the differences between the architecture of a bare-metal system and RTOS based system at a high level:

Figure 7.1: Arch

As can be seen, the RTOS (And associated middleware + libraries) captures a certain fixed size.

As a generalization, bare-metal systems typically have the advantage in that the system code overhead is small to start – but grows significantly as the application grows in complexity. At a certain point, it becomes extremely difficult and error-prone to add more functionality to an application running on such a system. There's a tipping point, where the cost of the code used to work-around the limitations of a bare-metal system outweigh the cost of a capable RTOS. Bare-metal systems also generally take longer to implement, because the system code has to be written from scratch (or derived from existing code) for the application. The resulting code also tend to be less portable, as it takes serious discipline to keep the system-specific elements of the code separated – in an RTOS-based system, once the kernel and drivers are ported, the application code is generally platform agnostic.

Conversely, an RTOS-based system incurs a slightly higher fixed cost up-front, but scales infinitely better than a bare-metal system as application's complexity increases. Using an RTOS for simple systems reduces application development time, but may cause an application not to fit into some extremely size-constrained microcontroller. An

RTOS can also cause the size of an application to grow more slowly relative to a bare-metal system – especially as a result of applying synchronization mechanisms and judicious IPC. As a result, an RTOS makes it significantly easier to “go agile” with an application – iteratively adding features and functionality, without having to consider refactoring the underlying system at each turn.

Some of these factors may be more important than others. Requirements, specifications, schedules, chip-selection, and volume projections for a project should all be used to feed into the discussions to decide whether or to go bare-metal or RTOS as a result.

Consider the following questions when making that decision:

- What is the application?
- How efficient is efficient enough?
- How fast is fast enough?
- How small is small enough?
- How responsive is responsive enough?
- How much code space/RAM/etc is available on the target system?
- How much code space/RAM do I need for an RTOS?
- How much code space/RAM do I think I'll need for my application?
- How much time do I have to deliver my system?
- How many units do we plan to sell?

7.2 Superloops, and their limitations

7.2.1 Intro to Superloops

Before we start taking a look at designing a real-time operating system, it's worthwhile taking a look through one of the most-common design patterns that developers use to manage task execution in bare-metal embedded systems - Superloops.

Systems based on superloops favor the system control logic baked directly into the application code, usually under the guise of simplicity, or memory (code and RAM) efficiency. For simple systems, superloops can definitely get the job done. However, they have some serious limitations, and are not suitable for every kind of project. In a lot of cases you can squeak by using superloops - especially in extremely constrained systems, but in general they are not a solid basis for reusable, portable code.

Nonetheless, a variety of examples are presented here- from the extremely simple, to cooperative and limited-preemptive multitasking systems, all of which are examples are representative of real-world systems that I've either written the firmware for, or have seen in my experience.

7.2.2 The simplest loop

Let's start with the simplest embedded system design possible - an infinite loop that performs a single task repeatedly:

```
int main()
{
    while(1)
    {
        Do_Something();
    }
}
```

Here, the code inside the loop will run a single function forever and ever. Not much to it, is there? But you might be surprised at just how much embedded system firmware is implemented using essentially the same mechanism - there isn't anything wrong with that, but it's just not that interesting.

Despite its simplicity we can see the beginnings of some core OS concepts. Here, the `while(1)` statement can be logically seen as the operating system kernel - this one control statement determines what tasks can run in the system, and defines the constraints that could modify their execution. But at the end of the day, that's a big part of what a kernel is - a mechanism that controls the execution of application code.

The second concept here is the task. This is application code provided by the user to perform some useful purpose in a system. In this case `Do_something()` represents that task - it could be monitoring blood pressure, reading a sensor and writing its data to a terminal, or playing an MP3; anything you can think of for an embedded system to do. A simple round-robin multi-tasking system can be built off of this example by simply adding additional tasks in sequence in the main `while`-loop. Note that in this example the CPU is always busy running tasks - at no time is the CPU idle, meaning that it is likely burning a lot of power.

While we conceptually have two separate pieces of code involved here (an operating system kernel and a set of running tasks), they are not logically separate. The OS code is indistinguishable from the application. It's like a single-celled organism - everything is crammed together within the walls of an indivisible unit; and specialized to perform its given function relying solely on instinct.

7.2.3 Interrupt-Driven Super-loop

In the previous example, we had a system without any way to control the execution of the task- it just runs forever. There's no way to control when the task can (or more importantly can't) run, which greatly limits the usefulness of the system. Say you only want your task to run every 100 milliseconds - in the previous code, you have to add a hard-coded delay at the end of your task's execution to ensure your code runs only when it should.

Fortunately, there is a much more elegant way to do this. In this example, we introduce the concept of the synchronization object. A Synchronization object is some data structure which works within the bounds of the operating system to tell tasks when they can run, and in many cases includes special data unique to the synchronization event.

There are a whole family of synchronization objects, which we'll get into later. In this example, we make use of the simplest synchronization primitive

- the global flag.

With the addition of synchronization brings the addition of event-driven systems. If you're programming a microcontroller system, you generally have scores of peripherals available to you - timers, GPIOs, ADCs, UARTs, ethernet, USB, etc. All of which can be configured to provide a stimulus to your system by means of interrupts. This stimulus gives us the ability not only to program our micros to `do_something()`, but to `do_something()` if-and-only-if a corresponding trigger has occurred.

The following concepts are shown in the example below:

```
volatile K_BOOL something_to_do = false;

__interrupt__ My_Interrupt_Source(void)
{
    something_to_do = true;
}

int main()
{
    while (1)
    {
        if (something_to_do)
        {
            Do_something();
            something_to_do = false;
        }
        else
        {
            Idle();
        }
    }
}
```

So there you have it - an event driven system which uses a global variable to synchronize the execution of our task based on the occurrence of an interrupt. It's still just a bare-metal, OS-baked-into-the-application system, but it's introduced a whole bunch of added complexity (and control!) into the system.

The first thing to notice in the source is that the global variable, `something_to_do`, is used as a synchronization object. When an interrupt occurs from some external event, triggering the `My_Interrupt_Source()` ISR, program flow in `main()` is interrupted, the interrupt handler is run, and `something_to_do` is set to true, letting us know that when we get back to `main()`, that we should run our `Do_something()` task.

Another new concept at play here is that of the idle function. In general, when running an event driven system, there are times when the CPU has no application tasks to run. In order to minimize power consumption, CPUs usually contain instructions or registers that can be set up to disable non-essential subsets of the system when there's nothing to do. In general, the sleeping system can be re-activated quickly as a result of an interrupt or other external stimulus, allowing normal processing to resume.

Now, we could just call `Do_something()` from the interrupt itself - but that's generally not a great solution. In general, the more time we spend inside an interrupt, the more time we spend with at least some interrupts disabled. As a result, we end up with interrupt latency. Now, in this system, with only one interrupt source and only one task this might not be a big deal, but say that `Do_something()` takes several seconds to complete, and in that time several other interrupts occur from other sources. While executing in our long-running interrupt, no other interrupts can be processed - in many cases, if two interrupts of the same type occur before the first is processed, one of these interrupt events will be lost. This can be utterly disastrous in a real-time system and should be avoided at all costs. As a result, it's generally preferable to use synchronization objects whenever possible to defer processing outside of the ISR.

Another OS concept that is implicitly introduced in this example is that of task priority. When an interrupt occurs, the normal execution of code in `main()` is preempted: control is swapped over to the ISR (which runs to completion), and then control is given back to `main()` where it left off. The very fact that interrupts take precedence over what's running shows that `main` is conceptually a "low-priority" task, and that all ISRs are "high-priority" tasks. In this example, our "high-priority" task is setting a variable to tell our "low-priority" task that it can do something useful. We will investigate the concept of task priority further in the next example.

Preemption is another key principle in embedded systems. This is the notion that whatever the CPU is doing when an interrupt occurs, it should stop, cache its current state (referred to as its context), and allow the high-priority event to be processed. The context of the previous task is then restored its state before the interrupt, and resumes processing. We'll come back to preemption frequently, since the concept comes up frequently in RTOS-based systems.

7.2.4 Cooperative multi-tasking

Our next example takes the previous example one step further by introducing cooperative multi-tasking:

```
// Bitfield values used to represent three distinct tasks
#define TASK_1_EVENT (0x01)
#define TASK_2_EVENT (0x02)
#define TASK_3_EVENT (0x04)

volatile K_UCHAR event_flags = 0;

// Interrupt sources used to trigger event execution

__interrupt__ My_Interrupt_1(void)
{
    event_flags |= TASK_1_EVENT;
}

__interrupt__ My_Interrupt_2(void)
{
    event_flags |= TASK_2_EVENT;
}

__interrupt__ My_Interrupt_3(void)
{
    event_flags |= TASK_3_EVENT;
}

// Main tasks
int main(void)
{

```

```

while(1)
{
    while(event_flags)
    {
        if( event_flags & TASK_1_EVENT)
        {
            Do_Task_1();
            event_flags &= ~TASK_1_EVENT;
        } else if( event_flags & TASK_2_EVENT) {
            Do_Task_2();
            event_flags &= ~TASK_2_EVENT;
        } else if( event_flags & TASK_3_EVENT) {
            Do_Task_3();
            event_flags &= ~TASK_3_EVENT;
        }
    }
    Idle();
}
}

```

This system is very similar to what we had before - however the differences are worth discussing. First, we have stimulus from multiple interrupt sources: each ISR is responsible for setting a single bit in our global event flag, which is then used to control execution of individual tasks from within main().

Next, we can see that tasks are explicitly given priorities inside the main loop based on the logic of the if/else if structure. As long as there is something set in the event flag, we will always try to execute Task1 first, and only when Task1 isn't set will we attempt to execute Task2, and then Task3. This added logic provides the notion of priority. However, because each of these tasks exist within the same context (they're just different functions called from our main control loop), we don't have the same notion of preemption that we have when dealing with interrupts.

That means that even through we may be running Task2 and an event flag for Task1 is set by an interrupt, the CPU still has to finish processing Task2 to completion before Task1 can be run. And that's why this kind of scheduling is referred to as cooperative multitasking: we can have as many tasks as we want, but unless they cooperate by means of returning back to main, the system can end up with high-priority tasks getting starved for CPU time by lower-priority, long-running tasks.

This is one of the more popular Os-baked-into-the-application approaches, and is widely used in a variety of real-time embedded systems.

7.2.5 Hybrid cooperative/preemptive multi-tasking

The final variation on the superloop design utilizes software-triggered interrupts to simulate a hybrid cooperative/preemptive multitasking system. Consider the example code below.

```

// Bitfields used to represent high-priority tasks. Tasks in this group
// can preempt tasks in the group below - but not eachother.
#define HP_TASK_1(0x01)
#define HP_TASK_2(0x02)

volatile K_UCHAR hp_tasks = 0;

// Bitfields used to represent low-priority tasks.
#define LP_TASK_1(0x01)
#define LP_TASK_2(0x02)

volatile K_UCHAR lp_tasks = 0;

// Interrupt sources, used to trigger both high and low priority tasks.
__interrupt__ System_Interrupt_1(void)
{
    // Set any of the other tasks from here...
    hp_tasks |= HP_TASK_1;
    // Trigger the SWI that calls the High_Priority_Tasks interrupt handler
    SWI();
}

__interrupt__ System_Interrupt_n...(void)
{
    // Set any of the other tasks from here...
}

// Interrupt handler that is used to implement the high-priority event context
__interrupt__ High_Priority_Tasks(void)
{

```

```

// Enabled every interrupt except this one
Disable_My_Interrupt();
Enable_Interrupts();
while( hp_tasks)
{
    if( hp_tasks & HP_TASK_1)
    {
        HP_Task1();
        hp_tasks &= ~HP_TASK_1;
    }
    else if (hp_tasks & HP_TASK_2)
    {
        HP_Task2();
        hp_tasks &= ~HP_TASK_2;
    }
}
Restore_Interrupts();
Enable_My_Interrupt();
}

// Main loop, used to implement the low-priority events
int main(void)
{
    // Set the function to run when a SWI is triggered
    Set_SWI(High_Priority_Tasks);

    // Run our super-loop
    while(1)
    {
        while (lp_tasks)
        {
            if (lp_tasks & LP_TASK_1)
            {
                LP_Task1();
                lp_tasks &= ~LP_TASK_1;
            }
            else if (lp_tasks & LP_TASK_2)
            {
                LP_Task2();
                lp_tasks &= ~LP_TASK_2;
            }
        }
        Idle();
    }
}

```

In this example, `High_Priority_Tasks()` can be triggered at any time as a result of a software interrupt (SWI),. When a high-priority event is set, the code that sets the event calls the SWI as well, which instantly preempts whatever is happening in main, switching to the high-priority interrupt handler. If the CPU is executing in an interrupt handler already, the current ISR completes, at which point control is given to the high priority interrupt handler.

Once inside the HP ISR, all interrupts (except the software interrupt) are re-enabled, which allows this interrupt to be preempted by other interrupt sources, which is called interrupt nesting. As a result, we end up with two distinct execution contexts (main and `HighPriorityTasks()`), in which all tasks in the high-priority group are guaranteed to preempt main() tasks, and will run to completion before returning control back to tasks in main(). This is a very basic preemptive multitasking scenario, approximating a "real" RTOS system with two threads of different priorities.

7.3 Problems with superloops

As mentioned earlier, a lot of real-world systems are implemented using a superloop design; and while they are simple to understand due to the limited and obvious control logic involved, they are not without their problems.

7.3.1 Hidden Costs

It's difficult to calculate the overhead of the superloop and the code required to implement workarounds for blocking calls, scheduling, and preemption. There's a cost in both the logic used to implement workarounds (usually involving state machines), as well as a cost to maintainability that comes with breaking up into chunks based on execution time instead of logical operations. In moderate firmware systems, this size cost can exceed the overhead of a reasonably well-featured RTOS, and the deficit in maintainability is something that is measurable in terms of lost productivity through debugging and profiling.

7.3.2 Tightly-coupled code

Because the control logic is integrated so closely with the application logic, a lot of care must be taken not to compromise the separation between application and system code. The timing loops, state machines, and architecture-specific control mechanisms used to avoid (or simulate) preemption can all contribute to the problem. As a result, a lot of superloop code ends up being difficult to port without effectively simulating or replicating the underlying system for which the application was written. Abstraction layers can mitigate the risks, but a lot of care should be taken to fully decouple the application code from the system code.

7.3.3 No blocking Calls

In a super-loop environment, there's no such thing as a blocking call or blocking objects. Tasks cannot stop mid-execution for event-driven I/O from other contexts - they must always run to completion. If busy-waiting and polling are used as a substitute, it increases latency and wastes cycles. As a result, extra code complexity is often times necessary to work-around this lack of blocking objects, often times through implementing additional state machines. In a large enough system, the added overhead in code size and cycles can add up.

7.3.4 Difficult to guarantee responsiveness

Without multiple levels of priority, it may be difficult to guarantee a certain degree of real-time responsiveness without added profiling and tweaking. The latency of a given task in a priority-based cooperative multitasking system is the length of the longest task. Care must be taken to break tasks up into appropriate sized chunks in order to ensure that higher- priority tasks can run in a timely fashion - a manual process that must be repeated as new tasks are added in the system. Once again, this adds extra complexity that makes code larger, more difficult to understand and maintain due to the artificial subdivision of tasks into time-based components.

7.3.5 Limited preemption capability

As shown in the example code, the way to gain preemption in a superloop is through the use of nested interrupts. While this isn't unwieldy for two levels of priority, adding more levels beyond this becomes complicated. In this case, it becomes necessary to track interrupt nesting manually, and separate sets of tasks that can run within given priority loops - and deadlock becomes more difficult to avoid.

Chapter 8

Can you afford an RTOS?

8.1 Intro

Of course, since you're reading the manual for an RTOS that I've been developing over the course of the several years, you can guess that the conclusion that I draw.

If your code is of any sort of non-trivial complexity (say, at least a few- thousand lines), then a more appropriate question would be "can you afford not* to use an RTOS in your system?".

In short, there are simply too many benefits of an RTOS to ignore, the most important being:

Threading, along with priority and time-based scheduling Sophisticated synchronization objects and IPC Flexible, powerful Software Timers Ability to write more portable, decoupled code

Sure, these features have a cost in code space and RAM, but from my experience the cost of trying to code around a lack of these features will cost you as much - if not more. The results are often far less maintainable, error prone, and complex. And that simply adds time and cost. Real developers ship, and the RTOS is quickly becoming one of the standard tools that help keep developers shipping.

One of the main arguments against using an RTOS in an embedded project is that the overhead incurred is too great to be justified. Concerns over "wasted" RAM caused by using multiple stacks, added CPU utilization, and the "large" code footprint from the kernel cause a large number of developers to shun using a preemptive RTOS, instead favoring a non-preemptive, application-specific solution.

I believe that not only is the impact negligible in most cases, but that the benefits of writing an application with an RTOS can lead to savings around the board (code size, quality, reliability, and development time). While these other benefits provide the most compelling case for using an RTOS, they are far more challenging to demonstrate in a quantitative way, and are clearly documented in numerous industry-based case studies.

While there is some overhead associated with an RTOS, the typical arguments are largely unfounded when an RTOS is correctly implemented in a system. By measuring the true overhead of a preemptive RTOS in a typical application, we will demonstrate that the impact to code space, RAM, and CPU usage is minimal, and indeed acceptable for a wide range of CPU targets.

To illustrate just how little an RTOS impacts the size of an embedded software design we will look at a typical microcontroller project and analyze the various types of overhead associated with using a pre-emptive realtime kernel versus a similar non-preemptive event-based framework.

RTOS overhead can be broken into three distinct areas:

- Code space: The amount of code space eaten up by the kernel (static)
- Memory overhead: The RAM associated with running the kernel and application threads.
- Runtime overhead: The CPU cycles required for the kernel's functionality (primarily scheduling and thread switching)

While there are other notable reasons to include or avoid the use of an RTOS in certain applications (determinism,

responsiveness, and interrupt latency among others), these are not considered in this discussion - as they are difficult to consider for the scope of our "canned" application.

8.2 Application description

For the purpose of this comparison, we first create an application using the standard preemptive Mark3 kernel with 2 system threads running: A foreground thread and a background thread. This gives three total priority levels in the system - the interrupt level (high), and two application priority threads (medium and low), which is quite a common paradigm for microcontroller firmware designs. The foreground thread processes a variety of time-critical events at a fixed frequency, while the background thread processes lower priority, aperiodic events. When there are no background thread events to process, the processor enters its low-power mode until the next interrupt is acknowledged.

The contents of the threads themselves are unimportant for this comparison, but we can assume they perform a variety of realtime I/O functions. As a result, a number of device drivers are also implemented.

Code Space and Memory Overhead:

The application is compiled for an ATmega328p processor which contains 32kB of code space in flash, and 2kB of RAM, which is a lower-mid-range microcontroller in Atmel's 8-bit AVR line of microcontrollers. Using the AVR GCC compiler with -Os level optimizations, an executable is produced with the following code/RAM utilization:

```
Program: 27914 bytes
Data:    1313 bytes
```

An alternate version of this project is created using a custom "super-loop" kernel, which uses a single application thread and provides 2 levels of priority (interrupt and application). In this case, the event handler processes the different priority application events to completion from highest to lowest priority.

This approach leaves the application itself largely unchanged. Using the same optimization levels as the preemptive kernel, the code compiles as follows:

```
Program: 24886 bytes
Data:    750 bytes
```

At first glance, the difference in RAM utilization seems quite a lot higher for the preemptive mode version of the application, but the raw numbers don't tell the whole story.

The first issue is that the cooperative-mode total does not take into account the system stack - whereas these values are included in the totals for RTOS version of the project. As a result, some further analysis is required to determine how the stack sizes truly compare.

In cooperative mode, there is only one thread of execution - so considering that multiple event handlers are executed in turn, the stack requirements for cooperative mode is simply determined by those of the most stack-intensive event handler (ignoring stack use contributions due to interrupts).

In contrast, the preemptive kernel requires a separate stack for each active thread, and as a result the stack usage of the system is the sum of the stacks for all threads.

Since the application and idle events are the same for both preemptive and cooperative mode, we know that their (independent) stack requirements will be the same in both cases.

For cooperative mode, we see that the idle thread stack utilization is lower than that of the application thread, and so the application thread's determines the stack size requirement. Again, with the preemptive kernel the stack utilization is the sum of the stacks defined for both threads.

As a result, the difference in overhead between the two cases becomes the extra stack required for the idle thread - which in our case is (a somewhat generous) 128 bytes.

The numbers still don't add up completely, but looking into the linker output we see that the rest of the difference comes from the extra data structures used to manage the kernel in preemptive mode, and the kernel data itself.

Fixed kernel data costs:

```
--- 134 Bytes Kernel data
--- 26 Bytes Kernel Vtables
```

Application (Variable) data costs:

```
--- 24 Bytes Driver Vtables
--- 123 Bytes - statically-allocated kernel objects (semaphores, timers, etc.)
```

With this taken into account, the true memory cost of a 2-thread system ends up being around 428 bytes of RAM - which is about 20% of the total memory available on this particular microcontroller. Whether or not this is reasonable certainly depends on the application, but more importantly, it is not so unreasonable as to eliminate an RTOS-based solution from being considered. Also note that by using the “simulated idle” feature provided in Mark3 R3 and onward, the idle thread (and its associated stack) can be eliminated altogether to reduce the cost in constrained devices.

The difference in code space overhead between the preemptive and cooperative mode solutions is less of an issue. Part of this reason is that both the preemptive and cooperative kernels are relatively small, and even an average target device (like the Atmega328 we’ve chosen) has plenty of room.

Mark3 can be configured so that only features necessary for the application are included in the RTOS - you only pay for the parts of the system that you use. In this way, we can measure the overhead on a feature-by-feature basis, which is shown below for the kernel as configured for this application:

```
Kernel ..... 2563 Bytes
Synchronization Objects. 644 Bytes
Port ..... 974 Bytes
Features ..... 871 Bytes
```

The configuration tested in this comparison uses the thread/port module with timers, drivers, and semaphores, and mutexes, for a total kernel size of 5052 Bytes, with the rest of the code space occupied by the application.

As can be seen from the compiler’s output, the difference in code space between the two versions of the application is 3028 bytes - or about 9% of the available code space on the selected processor. While nearly all of this comes from the added overhead of the kernel, the rest of the difference comes the changes to the application necessary to facilitate the different frameworks. This also demonstrates that the system-software code size in the cooperative case is about 2024 bytes.

8.3 Runtime Overhead

On the cooperative kernel, the overhead associated with running the thread is the time it takes the kernel to notice a pending event flag and launch the appropriate event handler, plus the timer interrupt execution time.

Similarly, on the preemptive kernel, the overhead is the time it takes to switch contexts to the application thread, plus the timer interrupt execution time.

The timer interrupt overhead is similar for both cases, so the overhead then becomes the difference between the following:

Preemptive mode:

- Posting the semaphore that wakes the high-priority thread
- Performing a context switch to the high-priority thread

Cooperative mode:

- Setting the event flag from the timer interrupt
- Acknowledging the event from the event loop

coop – 438 cycles preempt – 764 cycles

Using a cycle-accurate AVR simulator (fIAVR) running with a simulated speed of 16MHz, we find the end-to-end event sequence time to be 27us for the cooperative mode scheduler and 48us for the preemptive, and a raw difference of 20us.

With a fixed high-priority event frequency of 30Hz, we achieve a runtime overhead of 611us per second, or 0.06% of the total available CPU time. Now, obviously this value would expand at higher event frequencies and/or slower CPU frequencies, but for this typical application we find the difference in runtime overhead to be negligible for a preemptive system.

8.4 Analysis

For the selected test application and platform, including a preemptive RTOS is entirely reasonable, as the costs are low relative to a non-preemptive kernel solution. But these costs scale relative to the speed, memory and code space of the target processor. Because of these variables, there is no "magic bullet" environment suitable for every application, but Mark3 attempts to provide a framework suitable for a wide range of targets.

On the one hand, if these tests had been performed on a higher-end microcontroller such as the ATmega1284p (containing 128kB of code space and 16kB of RAM), the overhead would be in the noise. For this type of resource-rich microcontroller, there would be no reason to avoid using the Mark3 preemptive kernel.

Conversely, using a lower-end microcontroller like an ATmega88pa (which has only 8kB of code space and 1kB of RAM), the added overhead would likely be prohibitive for including a preemptive kernel. In this case, the cooperative-mode kernel would be a better choice.

As a rule of thumb, if one budgets 25% of a microcontroller's code space/RAM for system code, you should only require at minimum a microcontroller with 16k of code space and 2kB of RAM as a base platform for an RTOS. Unless there are serious constraints on the system that require much better latency or responsiveness than can be achieved with RTOS overhead, almost any modern platform is sufficient for hosting a kernel. In the event you find yourself with a microprocessor with external memory, there should be no reason to avoid using an RTOS at all.

Chapter 9

Mark3 Design Goals

9.1 Overview

9.1.1 Services Provided by an RTOS Kernel

At its lowest-levels, an operating system kernel is responsible for managing and scheduling resources within a system according to the application. In a typical thread-based RTOS, the resources involved is CPU time, and the kernel manages this by scheduling threads and timers. But capable RTOS kernels provide much more than just threading and timers.

In the following section, we discuss the Mark3 kernel architecture, all of its features, and a thorough discussion of how the pieces all work together to make an awesome RTOS kernel.

9.1.2 Guiding Principles of Mark3

Mark3 was designed with a number of over-arching principles, coming from years of experience designing, implementing, refining, and experimenting with RTOS kernels. Through that process I not only discovered what features I wanted in an RTOS, but how I wanted to build those features to look, work, and “feel”. With that understanding, I started with a clean slate and began designing a new RTOS. Mark3 is the result of that process, and its design goals can be summarized in the following guiding principles.

9.1.3 Be feature competitive

To truly be taken seriously as more than just a toy or educational tool, an RTOS needs to have a certain feature suite. While Mark3 isn't a clone of any existing RTOS, it should at least attempt parity with the most common software in its class.

Looking at its competitors, Mark3 as a kernel supports most, if not all of the compelling features found in modern RTOS kernels, including dynamic threads, tickless timers, efficient message passing, and multiple types of synchronization primitives.

9.1.4 Be highly configuration

Mark3 isn't a one-size-fits-all kernel – and as a result, it provides the means to build a custom kernel to suit your needs. By configuring the kernel at compile-time, Mark3 can be built to contain the optimal feature set for a given application. And since features can be configured individually, you only pay the code/RAM footprint for the features you actually use.

9.1.5 No external dependencies, no new language features

To maximize portability and promote adoption to new platforms, Mark3 is written in a widely supported subset of C++ that lends itself to embedded applications. It avoids RTTI, exceptions, templates, and libraries (C standard, STL, etc.), with all fundamental data structures and types implemented completely for use by the kernel. As a result, the portable parts of Mark3 should compile for any capable C++ toolchain.

9.1.6 Target the most popular hobbyist platforms available

Realistically, this means supporting the various Arduino-compatible target CPUs, including AVR and ARM Cortex-M series microcontrollers. As a result, the current default target for Mark3 is the atmega328p, which has 32KB of flash and 2KB of RAM. All decisions regarding default features, code size, and performance need to take that target system into account.

Mark3 integrates cleanly as a library into the Arduino IDE to support atmega328-based targets. Other AVR and Cortex-M targets can be supported using the port code provided in the source package.

9.1.7 Maximize determinism – but be pragmatic

Guaranteeing deterministic and predictable behavior is tough to do in an embedded system, and often comes with a heavy price tag in either RAM or code-space. With Mark3, we strive to keep the core kernel APIs and features as lightweight as possible, while avoiding algorithms that don't scale to large numbers of threads. We also achieve minimal latency by keeping interrupts enabled (operating out of the critical section) wherever possible.

In Mark3, the most important parts of the kernel are fixed-time, including thread scheduling and context switching. Operations that are not fixed time can be characterized as a function of their dependent data. For instances, the [Mutex](#) and [Semaphore](#) APIs operate in fixed time in the uncontested case, and execute in linear time for the contested case – where the speed of execution is dependent on the number of threads currently waiting on that object.

The caveat here is that while we want to minimize latency and time spent in critical sections, that has to be balanced against increases in code size, and uncontested-case performance.

9.1.8 Apply engineering principles – and that means discipline, measurement and verification

My previous RTOS, FunkOS, was designed to be very ad-hoc. The usage instructions were along the lines of “drag and drop the source files into your IDE and compile”. There was no regression/unit testing, no code size/speed profiling, and all documentation was done manually. It worked, but the process was a bit of a mess, and resulted in a lot of re-spins of the software, and a lot of time spent stepping through emulators to measure parameters.

We take a different approach in Mark3. Here, we've designed not only the kernel-code, but the build system, unit tests, profiling code, documentation and reporting that supports the kernel. Each release is built and tested using automation in order to ensure quality and correctness, with supporting documentation containing all critical metrics. Only code that passes testing is submitted to the repos and public forums for distribution. These metrics can be traced from build-to-build to ensure that performance remains consistent from one drop to the next, and that no regressions are introduced by new/refactored code.

And while the kernel code can still be exported into an IDE directly, that takes place with the knowledge that the kernel code has already been rigorously tested and profiled. Exporting source in Mark3 is also supported by scripting to ensure reliable, reproducible results without the possibility for human-error.

9.1.9 Use Virtualization For Verification

Mark3 was designed to work with automated simulation tools as the primary means to validate changes to the kernel, due to the power and flexibility of automatic tests on virtual hardware. I was also intrigued by the thought of extending the virtual target to support functionality useful for a kernel, but not found on real hardware.

When the project was started, simavr was the tool of choice- however, its simulation was found to be incorrect compared to execution on a real MCU, and it did not provide the degree of extension that I desired for use with kernel development.

The flAVR AVR simulator was written to replace the dependency on that tool, and overcome those limitations. It also provides a GDB interface, as well as its own built-in debugger, profilers, and trace tools.

The example and test code relies heavily on flAVR kernel aware messaging, so it is recommended that you familiarize yourself with that tool if you intend to do any sort of customizations or extensions to the kernel.

flAVR is hosted on sourceforge at <http://www.sourceforge.net/projects/flavr/> . In its basic configuration, it builds with minimal external dependencies.

- On linux, it requires only pthreads.
- On Windows, it requires pthreads and ws2_32, both satisfied via MinGW.
- Optional SDL builds for both targets (featuring graphics and simulated joystick input) can be built, and rely on libSDL.

Chapter 10

Mark3 Kernel Architecture

10.1 Overview

At a high level, the Mark3 RTOS is organized into the following features, and layered as shown below:

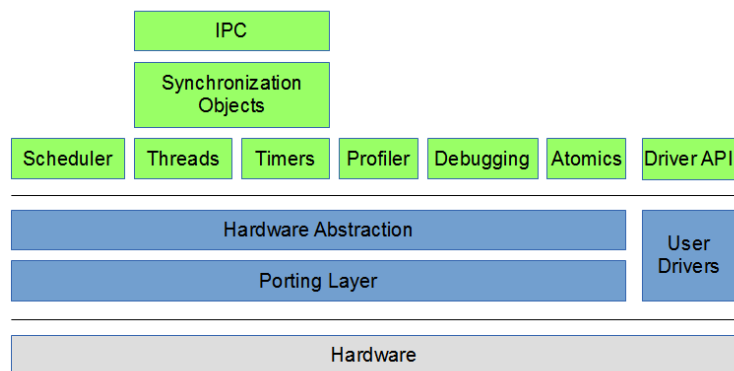

Figure 10.1: Overview

Everything in the “green” layer represents the Mark3 public API and classes, beneath which lives all hardware abstraction and CPU-specific porting and driver code, which runs on a given target CPU.

The features and concepts introduced in this diagram can be described as follows:

Threads: The ability to multiplex the CPU between multiple tasks to give the perception that multiple programs are running simultaneously. Each thread runs in its own context with its own stack.

Scheduler: Algorithm which determines the thread that gets to run on the CPU at any given time. This algorithm takes into account the priorities (and other execution parameters) associated with the threads in the system.

IPC: Inter-process-communications. Message-passing and [Mailbox](#) interfaces used to communicate between threads synchronously or asynchronously.

Synchronization Objects: Ability to schedule thread execution relative to system conditions and events, allowing for sharing global data and resources safely and effectively.

Timers: High-resolution software timers that allow for actions to be triggered on a periodic or one-shot basis.

Profiler: Special timer used to measure the performance of arbitrary blocks of code.

Debugging: Realtime logging and trace functionality, facilitating simplified debugging of systems using the OS.

Atomics: Support for UN-interruptible arithmetic operations.

Driver API: Hardware abstraction interface allowing for device drivers to be written in a consistent, portable manner.

Hardware Abstraction Layer: Class interface definitions to represent threading, context-switching, and timers in a generic, abstracted manner.

Porting Layer: Class interface implementation to support threading, context-switching, and timers for a given CPU.

User Drivers: Code written by the user to implement device-specific peripheral drivers, built to make use of the Mark3 driver API.

Each of these features will be described in more detail in the following sections of this chapter.

The concepts introduced in the above architecture are implemented in a variety of source modules, which are logically broken down into classes (or in some cases, groups of functions/macros). The relationship between objects in the Mark3 kernel is shown below:

Figure 10.2: Overview

The objects shown in the preceding table can be grouped together by feature. In the table below, we group each feature by object, referencing the source module in which they can be found in the Mark3 source tree.

Feature	Kernel Object	Source Files
Profiling	ProfileTimer	profile.cpp/.h
Threads + Scheduling	Thread	thread.cpp/.h
	Scheduler	scheduler.cpp/.h
	PriorityMap	priomap.cpp/.h
	Quantum	quantum.cpp/.h
	ThreadPort	threadport.cpp/.h **
	KernelSWI	kernelswi.cpp/.h **
Timers	Timer	timer.h/timer.cpp
	TimerScheduler	timerscheduler.h
	TimerList	timerlist.h/cpp

Let's look at a very basic CPU without any sort of special multi-threading hardware, and without interrupts. When the CPU is powered up, the program counter is loaded with some default location, at which point the processor core will start executing instructions sequentially - running forever and ever according to whatever has been loaded into program memory. This single instance of a simple program sequence is the only thing that runs on the processor, and the execution of the program can be predicted entirely by looking at the CPU's current register state, its program, and any affected system memory (the CPU's "context").

It's simple enough, and that's exactly the definition we have for a thread in an RTOS.

Each thread contains an instance of a CPU's register context, its own stack, and any other bookkeeping information necessary to define the minimum unique execution state of a system at runtime. It is the job of a RTOS to multiplex the execution of multiple threads on a single physical CPU, thereby creating the illusion that many programs are being executed simultaneously. In reality there can only ever be one thread truly executing at any given moment on a CPU core, so it's up to the scheduler to set and enforce rules about what thread gets to run when, for how long, and under what conditions. As mentioned earlier, any system without an RTOS executes as a single thread, so at least two threads are required for an RTOS to serve any useful purpose.

Note that all of this information is common to pretty well every RTOS in existence - the implementation details, including the scheduler rules, are all part of what differentiates one RTOS from another.

10.2.2 Thread States and ThreadLists

Since only one thread can run on a CPU at a time, the scheduler relies on thread information to make its decisions. Mark3's scheduler relies on a variety of such information, including:

- The thread's current priority
- Round-Robin execution quanta
- Whether or not the thread is blocked on a synchronization object, such as a mutex or semaphore
- Whether or not the thread is currently suspended

The scheduler further uses this information to logically place each thread into 1 of 4 possible states:

- Ready - The thread is currently running
- Running - The thread is able to run
- Blocked - The thread cannot run until a system condition is met
- Stopped - The thread cannot run because its execution has been suspended

In order to determine a thread's state, threads are placed in "buckets" corresponding to these states. Ready and running threads exist in the scheduler's buckets, blocked threads exist in a bucket belonging to the object they're blocked on, and stopped threads exist in a separate bucket containing all stopped threads.

In reality, the various buckets are just doubly-linked lists of [Thread](#) objects - implemented in something called the [ThreadList](#) class. To facilitate this, the [Thread](#) class directly inherits from a [LinkListNode](#) class, which contains the node pointers required to implement a doubly-linked list. As a result, Threads may be effortlessly moved from one state to another using efficient linked-list operations built into the [ThreadList](#) class.

10.2.3 Blocking and Unblocking

While many developers new to the concept of an RTOS assume that all threads in a system are entirely separate from each other, the reality is that practical systems typically involve multiple threads working together, or at the very least sharing resources. In order to synchronize the execution of threads for that purpose, a number of synchronization primitives (blocking objects) are implemented to create specific sets of conditions under which threads can continue execution. The concept of "blocking" a thread until a specific condition is met is fundamental to understanding RTOS applications design, as well as any highly-multithreaded applications.

10.2.4 Blocking Objects

Blocking objects and primitives provided by Mark3 include:

- Semaphores (binary and counting)
- Mutexes
- Event Flags
- [Thread](#) Notification Objects
- [Thread](#) Sleep
- [Message](#) Queues
- Mailboxes

The relationship between these objects in the system are shown below:

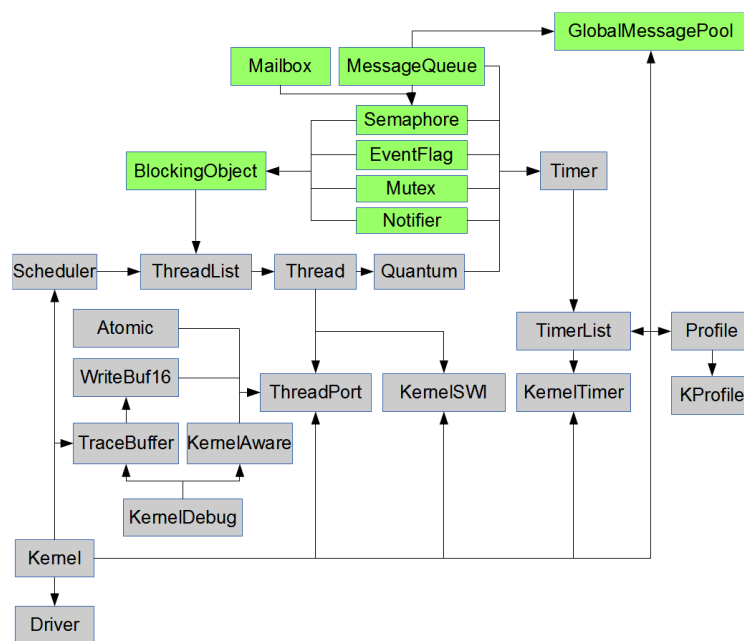

Figure 10.4: Blocking Objects

Each of these objects inherit from the [BlockingObject](#) class, which itself contains a [ThreadList](#) object. This class contains methods to `Block()` a thread (remove it from the [Scheduler](#)'s "Ready" or "Running" ThreadLists), as well as `UnBlock()` a thread (move a thread back to the "Ready" lists). This object handles transitioning threads from list-to-list (and state-to-state), as well as taking care of any other [Scheduler](#) bookkeeping required in the process. While each of the Blocking types implement a different condition, they are effectively variations on the same theme. Many simple Blocking objects are also used to build complex blocking objects - for instance, the [Thread](#) Sleep mechanism is essentially a binary semaphore and a timer object, while a message queue is a linked-list of message objects combined with a semaphore.

10.3 Inside the Mark3 Scheduler

At this point we've covered the following concepts:

- Threads
- [Thread](#) States and [Thread](#) Lists
- Blocking and Un-Blocking Threads

Thankfully, this is all the background required to understand how the Mark3 [Scheduler](#) works. In technical terms, Mark3 implements "strict priority scheduling, with round-robin scheduling among threads in each priority group". In plain English, this boils down to a scheduler which follows a few simple rules:

```
Find the highest-priority "Ready" list that has at least one Threads.
If the first thread in that bucket is not the current thread, select it
to run next. Otherwise, rotate the linked list, and choose the next
thread in the list to run
```

Since context switching is one of the most common and frequent operation performed by an RTOS, this needs to be as fast and deterministic as possible. While the logic is simple, a lot of care must be put into optimizing the scheduler to achieve those goals. In the section below we discuss the optimization approaches taken in Mark3.

There are a number of ways to find the highest-priority thread. The naive approach would be to simply iterate through the scheduler's array of ThreadLists from highest to lowest, stopping when the first non-empty list is found, such as in the following block of code:

```
for (prio = num_prio - 1; prio >= 0; prio--)
{
    if (thread_list[prio].get_head() != NULL)
    {
        break;
    }
}
```

While that would certainly work and be sufficient for a variety of systems, it's a non-deterministic approach (complexity $O(n)$) whose cost varies substantially based on how many priorities have to be evaluated. It's simple to read and understand, but it's non-optimal.

Fortunately, a functionally-equivalent and more deterministic approach can be implemented with a few tricks.

In addition to maintaining an array of ThreadLists, Mark3 also maintains a bitmap (one bit per priority level) that indicates which thread lists have ready threads. This bitmap is maintained automatically by the [ThreadList](#) class, and is updated every time a thread is moved to/from the [Scheduler's](#) ready lists.

By inspecting this bitmap using a technique to count the leading zero bits in the bitmap, we determine which threadlist to choose in fixed time.

Now, to implement the leading-zeros check, this can once again be performed iteratively using bitshifts and compares (which isn't any more efficient than the raw list traversal), but it can also be evaluated using either a lookup table, or via a special CPU instruction to count the leading zeros in a value. In Mark3, we opt for the lookup-table approach since we have a limited number of priorities and not all supported CPU architectures support a count leading zero instruction. To achieve a balance between performance and memory use, we use a 4-bit lookup table (costing 16 bytes) to perform the lookup.

(As a sidenote - this is actually a very common approach in OS schedulers. It's actually part of the reason why modern ARM cores implement a dedicated count-leading-zeros [CLZ] instruction!)

With a 4-bit lookup table and an 8-bit priority-level bitmap, the priority check algorithm looks something like this:

```
// Check the highest 4 priority levels, represented in the
// upper 4 bits in the bitmap
priority = priority_lookup_table[(priority_bitmap >> 4)];

// priority is non-zero if we found something there
if( priority )
```

```

{
    // Add 4 because we were looking at the higher levels
    priority += 4;
}
else
{
    // Nothing in the upper 4, look at the lowest 4 priority levels
    // represented by the lowest 4 bits in the bitmap
    priority = priority_lookup_table[priority_bitmap & 0x0F];
}

```

Deconstructing this algorithm, you can see that the priority lookup will have an $O(1)$ complexity - and is extremely low-cost.

This operation is thus fully deterministic and time bound - no matter how many threads are scheduled, the operation will always be time-bound to the most expensive of these two code paths. Even with only 8 priority levels, this is still much faster than iteratively checking the thread lists manually, compared with the previous example implementation.

Once the priority level has been found, selecting the next thread to run is trivial, consisting of something like this:

```
next_thread = thread_list[prio].get_head();
```

In the case of the `get_head()` calls, this evaluates to an inline-load of the "head" pointer in the particular thread list.

One important thing to take away from this analysis is that the scheduler is only responsible for selecting the next-to-run thread. In fact, these two operations are totally decoupled - no context switching is performed by the scheduler, and the scheduler isn't called from the context switch. The scheduler simply produces new "next thread" values that are consumed from within the context switch code.

10.3.1 Considerations for Round-Robin Scheduling

One thing that isn't considered directly from the scheduler algorithm is the problem of dealing with multiple threads within a single priority group; all of the algorithms that have been explored above simply look at the first [Thread](#) in each group.

Mark3 addresses this issue indirectly, using a software timer to manage round-robin scheduling, as follows.

In some instances where the scheduler is run by the kernel directly (typically as a result of calling [Thread::Yield\(\)](#)), the kernel will perform an additional check after running the [Scheduler](#) to determine whether or there are multiple ready [Threads](#) in the priority of the next ready thread.

If there are multiple threads within that priority, the kernel adds a one-shot software timer which is programmed to expire at the next [Thread](#)'s configured quantum. When this timer expires, the timer's callback function executes to perform two simple operations:

"Pivot" the current [Thread](#)'s priority list. Set a flag telling the kernel to trigger a Yield after exiting the main [Timer](#)↔[Scheduler](#) processing loop

Pivoting the thread list basically moves the head of a circular-linked-list to its next value, which in our case ensures that a new thread will be chosen the next time the scheduler is run (the scheduler only looks at the head node of the priority lists). And by calling `Yield`, the system forces the scheduler to run, a new round-robin software timer to be installed (if necessary), and triggers a context switch SWI to load the newly-chosen thread. Note that if the thread attached to the round-robin timer is pre-empted, the kernel will take steps to abort and invalidate that round-robin software timer, installing a new one tied to the next thread to run if necessary.

Because the round-robin software timer is dynamically installed when there are multiple ready threads at the highest ready priority level, there is no CPU overhead with this feature unless that condition is met. The cost of round-robin scheduling is also fixed - no matter how many threads there are, and the cost is identical to any other one-shot software timer in the system.

10.3.2 Context Switching

There's really not much to say about the actual context switch operation at a high level. Context switches are triggered whenever it has been determined that a new thread needs to be swapped into the CPU core when the scheduler is run. Mark3 implements also context switches as a call to a software interrupt - on AVR platforms, we

typically use INT0 or INT2 for this (although any pin-change GPIO interrupt can be used), and on ARM we achieve this by triggering a PendSV exception.

However, regardless of the architecture, the context-switch ISR will perform the following three operations:

Save the current [Thread](#)'s context to the current [Thread](#) stack
Make the "next to run" thread the "currently running" thread
Restore the context of the next [Thread](#) from the [Thread](#) stack

The code to implement the context switch is entirely architecture-specific, so it won't be discussed in detail here. It's almost always gory inline-assembly which is used to load and store various CPU registers, and is highly-optimized for speed. We dive into an example implementation for the ARM Cortex-M0 microcontroller in a later section of this book.

10.3.3 Putting It All Together

In short, we can say that the Mark3 scheduler works as follows:

- The scheduler is run whenever a [Thread::Yield\(\)](#) is called by a user, as part of blocking calls, or whenever a new thread is started
- The Mark3 scheduler is deterministic, selecting the next thread to run in fixed-time
- The scheduler only chooses the next thread to run, the context switch SWI consumes that information to get that thread running
- Where there are multiple ready threads in the highest populated priority level, a software timer is used to manage round-robin scheduling

While we've covered a lot of ground in this section, there's not a whole lot of code involved. However, the code that performs these operations is nuanced and subtle. If you're interested in seeing how this all works in practice, I suggest reading through the Mark3 source code (which is heavily annotated), and stepping through the code with a simulator/emulator.

10.4 Timers

Mark3 implements one-shot and periodic software-timers via the [Timer](#) class. The user configures the timer for duration, repetition, and action, at which point the timer can be activated. When an active timer expires, the kernel calls a user-specified callback function, and then reloads the timer in the case of periodic timers. The same timer objects exposed to the user are also used within the kernel to implement round-robin scheduling, and timeout-based APIs for semaphores, mutexes, events, and messages.

Timers are implemented using the following components in the Mark3 [Kernel](#):

10.4.1 Tick-based Timers

In a tick-based timing scheme, the kernel relies on a system-timer interrupt to fire at a relatively-high frequency, on which all kernel timer events are derived. On modern CPUs and microcontrollers, a 1kHz system tick is common, although quite often lower frequencies such as 60Hz, 100Hz, or 120Hz are used. The resolution of this timer also defines the maximum resolution of timer objects as a result. That is, if the timer frequency is 1kHz, a user cannot specify a timer resolution lower than 1ms.

The advantage of a tick-based timer is its sheer simplicity. It typically doesn't take much to set up a timer to trigger an interrupt at a fixed-interval, at which point, all system timer intervals are decremented by 1 count. When each system timer interval reaches zero, a callback is called for the event, and the events are either reset and restarted (repeated timers) or cleared (1-shot).

Unfortunately, that simplicity comes at a cost of increased interrupt count, which cause frequent CPU wakeups and utilization, and power consumption.

10.4.2 Tickless Timers

In a tickless system, the kernel timer only runs when there are active timers pending expiry, and even then, the timer module only generates interrupts when a timer expires, or a timer reaches its maximum count value. Additionally, when there are no active timer objects, the timer can be completely disabled – saving even more cycles, power, and CPU wakeups. These factors make the tickless timer approach a highly-optimal solution, suitable for a wide array of low-power applications.

Also, since tickless timers do not rely on a fixed, periodic clock, they can potentially be higher resolution. The only limitation in timer resolution is the precision of the underlying hardware timer as configured. For example, if a 32kHz hardware timer is being used to drive the timer scheduler, the resolution of timer objects would be in the $\sim 33\mu\text{s}$ range.

The only downside of the tickless timer system is an added complexity to the timer code, requiring more code space, and slightly longer execution of the timer routines when the timer interrupt is executed.

10.4.3 Timer Processing Algorithm

Timer interrupts occur at either a fixed-frequency (tick-based), or at the next timer expiry interval (tickless), at which point the timer processing algorithm runs. While the timer count is reset by the timer-interrupt, it is still allowed to accumulate ticks while this algorithm is executed in order to ensure that timer-accuracy is kept in real-time. It is also important to note that round-robin scheduling changes are disabled during the execution of this algorithm to prevent race conditions, as the round-robin code also relies on timer objects.

All active timer objects are stored in a doubly-linked list within the timer-scheduler, and this list is processed in two passes by the algorithm which runs from the timer-interrupt (with interrupt nesting enabled). The first pass determines which timers have expired and the next timer interval, while the second pass deals with executing the timer callbacks themselves. Both phases are discussed in more detail below.

In the first pass, the active timers are decremented by either 1 tick (tick-based), or by the duration of the last elapsed timer interval (tickless). Timers that have zero (or less-than-zero) time remaining have a "callback" flag set, telling the algorithm to call the timer's callback function in the second pass of the loop. In the event of a periodic timer, the timer's interval is reset to its starting value.

For the tickless case, the next timer interval is also computed in the first-pass by looking for the active timer with the least amount of time remaining in its interval. Note that this calculation is irrelevant in the tick-based timer code, as the timer interrupt fires at a fixed-frequency.

In the second pass, the algorithm loops through the list of active timers, looking for those with their "callback" flag set in the first pass. The callback function is then executed for each expired timer, and the "callback" flag cleared. In the event that a non-periodic (one-shot) timer expires, the timer is also removed from the timer scheduler at this time.

In a tickless system, once the second pass of the loop has been completed, the hardware timer is checked to see if the next timer interval has expired while processing the expired timer callbacks. In that event, the complete

algorithm is re-run to ensure that no expired timers are missed. Once the algorithm has completed without the next timer expiring during processing, the expiry time is programmed into the hardware timer. Round-robin scheduling is re-enabled, and if a new thread has been scheduled as a result of action taken during a timer callback, a context switch takes place on return from the timer interrupt.

10.5 Synchronization and IPC

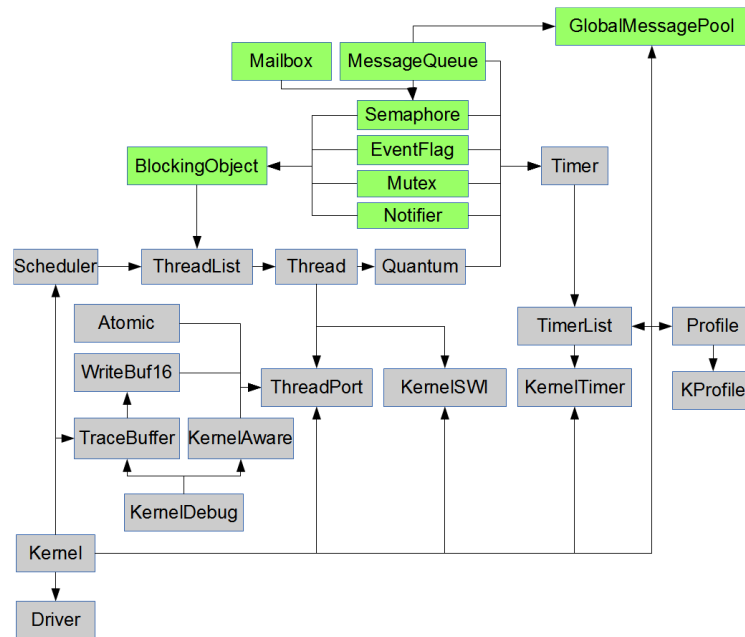

Figure 10.6: Synchronization and IPC

10.6 Blocking Objects

A Blocking object in Mark3 is essentially a thread list. Any blocking object implementation (being a semaphore, mutex, event flag, etc.) can be built on top of this class, utilizing the provided functions to manipulate thread location within the [Kernel](#).

Blocking a thread results in that thread becoming de-scheduled, placed in the blocking object's own private list of threads which are waiting on the object.

Unblocking a thread results in the reverse: The thread is moved back to its original location from the blocking list.

The only difference between a blocking object based on this class is the logic used to determine what constitutes a Block or Unblock condition.

For instance, a semaphore Pend operation may result in a call to the Block() method with the currently-executing thread in order to make that thread wait for a semaphore Post. That operation would then invoke the Unblock() method, removing the blocking thread from the semaphore's list, and back into the appropriate thread inside the scheduler.

Care must be taken when implementing blocking objects to ensure that critical sections are used judiciously, otherwise asynchronous events like timers and interrupts could result in non-deterministic and often catastrophic behavior.

Mark3 implements a variety of blocking objects including semaphores, mutexes, event flags, and IPC mechanisms that all inherit from the basic Blocking-object class found in [blocking.h/cpp](#), ensuring consistency and a high degree of code-reuse between components.

10.6.1 Semaphores

Semaphores are used to synchronized execution of threads based on the availability (and quantity) of application-specific resources in the system. They are extremely useful for solving producer-consumer problems, and are the method-of-choice for creating efficient, low latency systems, where ISRs post semaphores that are handled from within the context of individual threads. Semaphores can also be posted (but not pended) from within the interrupt context.

10.6.2 Mutex

Mutexes (Mutual exclusion objects) are provided as a means of creating "protected sections" around a particular resource, allowing for access of these objects to be serialized. Only one thread can hold the mutex at a time

- other threads have to wait until the region is released by the owner thread before they can take their turn operating on the protected resource. Note that mutexes can only be owned by threads - they are not available to other contexts (i.e. interrupts). Calling the mutex APIs from an interrupt will cause catastrophic system failures.

Note that these objects are recursive in Mark3 - that is, the owner thread can claim a mutex more than once. The caveat here is that a recursively-held mutex will not be released until a matching "release" call is made for each "claim" call.

Priority inheritance is provided with these objects as a means to avoid priority inversions. Whenever a thread at a priority than the mutex owner blocks on a mutex, the priority of the current thread is boosted to the highest-priority waiter to ensure that other tasks at intermediate priorities cannot artificially prevent progress from being made.

10.6.3 Event Flags

Event Flags are another synchronization object, conceptually similar to a semaphore.

Unlike a semaphore, however, the condition on which threads are unblocked is determined by a more complex set of rules. Each Event Flag object contains a 16-bit field, and threads block, waiting for combinations of bits within this field to become set.

A thread can wait on any pattern of bits from this field to be set, and any number of threads can wait on any number of different patterns. Threads can wait on a single bit, multiple bits, or bits from within a subset of bits within the field.

As a result, setting a single value in the flag can result in any number of threads becoming unblocked simultaneously. This mechanism is extremely powerful, allowing for all sorts of complex, yet efficient, thread synchronization schemes that can be created using a single shared object.

Note that Event Flags can be set from interrupts, but you cannot wait on an event flag from within an interrupt.

10.6.4 Notification Objects

Notification objects are the most lightweight of all blocking objects supplied by Mark3.

using this blocking primitive, one or more threads wait for the notification object to be signalled by code elsewhere in the system (i.e. another thread or interrupt). Once the notification has been signalled, all threads currently blocked on the object become unblocked and moved into the ready list.

Signalling a notification object that has no actively-waiting threads has no effect.

10.7 Messages and Global Message Queue

10.7.1 Messages

Sending messages between threads is the key means of synchronizing access to data, and the primary mechanism to perform asynchronous data processing operations.

Sending a message consists of the following operations:

- Obtain a [Message](#) object from the global message pool
- Set the message data and event fields
- Send the message to the destination message queue

While receiving a message consists of the following steps:

- Wait for a messages in the destination message queue
- Process the message data
- Return the message back to the global message pool

These operations, and the various data objects involved are discussed in more detail in the following section.

10.7.2 Message Objects

[Message](#) objects are used to communicate arbitrary data between threads in a safe and synchronous way.

The message object consists of an event code field and a data field. The event code is used to provide context to the message object, while the data field (essentially a void * data pointer) is used to provide a payload of data corresponding to the particular event.

Access to these fields is marshalled by accessors - the transmitting thread uses the `SetData()` and `SetCode()` methods to seed the data, while the receiving thread uses the `GetData()` and `GetCode()` methods to retrieve it.

By providing the data as a void data pointer instead of a fixed-size message, we achieve an unprecedented measure of simplicity and flexibility. Data can be either statically or dynamically allocated, and sized appropriately for the event without having to format and reformat data by both sending and receiving threads. The choices here are left to the user - and the kernel doesn't get in the way of efficiency.

It is worth noting that you can send messages to message queues from within ISR context. This helps maintain consistency, since the same APIs can be used to provide event-driven programming facilities throughout the whole of the OS.

10.7.3 Global Message Pool

To maintain efficiency in the messaging system (and to prevent over-allocation of data), a global pool of message objects is provided. The size of this message pool is specified in the implementation, and can be adjusted depending on the requirements of the target application as a compile-time option.

Allocating a message from the message pool is as simple as calling the

[GlobalMessagePool::Pop\(\)](#) Method.

Messages are returned back to the [GlobalMessagePool::Push\(\)](#) method once the message contents are no longer required.

One must be careful to ensure that discarded messages always are returned to the pool, otherwise a resource leak will occur, which may cripple the operating system's ability to pass data between threads.

10.7.4 Message Queues

[Message](#) objects specify data with context, but do not specify where the messages will be sent. For this purpose we have a [MessageQueue](#) object. Sending an object to a message queue involves calling the [MessageQueue::Send\(\)](#) method, passing in a pointer to the [Message](#) object as an argument.

When a message is sent to the queue, the first thread blocked on the queue (as a result of calling the [MessageQueue Receive\(\)](#) method) will wake up, with a pointer to the [Message](#) object returned.

It's worth noting that multiple threads can block on the same message queue, providing a means for multiple threads to share work in parallel.

10.7.5 Mailboxes

Another form of IPC is provided by Mark3, in the form of Mailboxes and Envelopes. Mailboxes are similar to message queues in that they provide a synchronized interface by which data can be transmitted between threads.

Where [Message](#) Queues rely on linked lists of lightweight message objects (containing only message code and a void* data-pointer), which are inherently abstract, Mailboxes use a dedicated blob of memory, which is carved up into fixed-size chunks called Envelopes (defined by the user), which are sent and received. Unlike message queues, mailbox data is copied to and from the mailboxes dedicated pool.

Mailboxes also differ in that they provide not only a blocking "receive" call, but also a blocking "send" call, providing the opportunity for threads to block on "mailbox full" as well as "mailbox empty" conditions.

All send/receive APIs support an optional timeout parameter if the `KERNEL_USE_TIMEOUTS` option has been configured in [mark3cfg.h](#)

10.7.6 Atomic Operations

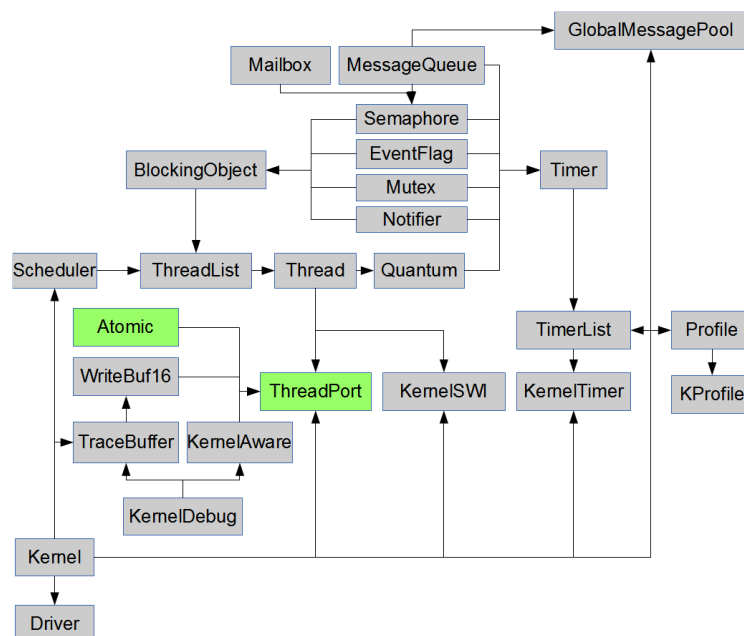

Figure 10.7: Atomic operations

This utility class provides primitives for atomic operations - that is, operations that are guaranteed to execute uninterrupted. Basic atomic primitives provided here include Set/Add/Delete for 8, 16, and 32-bit integer types, as well as an atomic test-and-set.

10.7.7 Drivers

Figure 10.8: Drivers

This is the basis of the driver framework. In the context of Mark3, drivers don't necessarily have to be based on physical hardware peripherals. They can be used to represent algorithms (such as random number generators), files, or protocol stacks. Unlike FunkOS, where driver IO is protected automatically by a mutex, we do not use this kind of protection - we leave it up to the driver implementor to do what's right in its own context. This also frees up the driver to implement all sorts of other neat stuff, like sending messages to threads associated with the driver. Drivers are implemented as character devices, with the standard array of posix-style accessor methods for reading, writing, and general driver control.

A global driver list is provided as a convenient and minimal "filesystem" structure, in which devices can be accessed by name.

Driver Design

A device driver needs to be able to perform the following operations:

- Initialize a peripheral
- Start/stop a peripheral
- Handle I/O control operations
- Perform various read/write operations

At the end of the day, that's pretty much all a device driver has to do, and all of the functionality that needs to be presented to the developer.

We abstract all device drivers using a base-class which implements the following methods:

- Start/Open
- Stop/Close
- Control
- Read
- Write

A basic driver framework and API can thus be implemented in five function calls - that's it! You could even reduce that further by handling the initialize, start, and stop operations inside the "control" operation.

Driver API

In C++, we can implement this as a class to abstract these event handlers, with virtual void functions in the base class overridden by the inherited objects.

To add and remove device drivers from the global table, we use the following methods:

```
void DriverList::Add( Driver *pclDriver_ );
void DriverList::Remove( Driver *pclDriver_ );
```

`DriverList::Add()/Remove()` takes a single argument - the pointer to the object to operate on.

Once a driver has been added to the table, drivers are opened by NAME using `DriverList::FindByName("/dev/name")`. This function returns a pointer to the specified driver if successful, or to a built in /dev/null device if the path name is invalid. After a driver is open, that pointer is used for all other driver access functions.

This abstraction is incredibly useful - any peripheral or service can be accessed through a consistent set of APIs, that make it easy to substitute implementations from one platform to another. Portability is ensured, the overhead is negligible, and it emphasizes the reuse of both driver and application code as separate entities.

Consider a system with drivers for I2C, SPI, and UART peripherals - under our driver framework, an application can initialize these peripherals and write a greeting to each using the same simple API functions for all drivers:

```
pclI2C = DriverList::FindByName("/dev/i2c");
pclUART = DriverList::FindByName("/dev/tty0");
pclSPI = DriverList::FindByName("/dev/spi");

pclI2C->Write(12, "Hello World!");
pclUART->Write(12, "Hello World!");
pclSPI->Write(12, "Hello World!");
```

This section serves as a real-world example of how Mark3 can be ported to new architectures, how the Mark3 abstraction layer works, and as a practical reference for using the RTOS support functionality baked in modern ARM Cortex-M series microcontrollers. Most of this documentation here is taken directly from the source code found in the `/kernel/cpu/cm0/ports` directory, with additional annotations to explain the port in more detail. Note that a familiarity with Cortex-M series parts will go a long way to understanding the subject matter presented, especially a basic understanding of the ARM CPU registers, exception models, and OS support features (PendSV, SysTick and SVC). If you're unfamiliar with ARM architecture, pay attention to the comments more than the source itself to illustrate the concepts.

Porting Mark3 to a new architecture consists of a few basic pieces; for developers familiar with the target architecture and the porting process, it's not a tremendously onerous endeavour to get Mark3 up-and-running somewhere new. For starters, all non-portable components are completely isolated in the source-tree under:

```
/embedded/kernel/CPU/VARIANT/TOOLCHAIN/
```

where CPU is the architecture, VARIANT is the vendor/part, and TOOLCHAIN is the compiler tool suite used to build the code.

From within the specific port folder, a developer needs only implement a few classes and headers that define the port-specific behavior of Mark3:

- [KernelSWI](#) ([kernelswi.cpp](#)/[kernelswi.h](#)) - Provides a maskable software-triggered interrupt used to perform context switching.
- [KernelTimer](#) ([kerneltimer.cpp](#)/[kerneltimer.h](#)) - Provides either a fixed-frequency or programmable-interval timer, which triggers an interrupt on expiry. This is used for implementing round-robin scheduling, thread-sleeps, and generic software timers.
- [Profiler](#) ([kprofile.cpp](#)/[kprofile.h](#)) - Contains code for runtime code-profiling. This is optional and may be stubbed out if left unimplemented (we won't cover profiling timers here).
- [ThreadPort](#) ([threadport.cpp](#)/[threadport.h](#)) - The meat-and-potatoes of the port code lives here. This class contains architecture/part-specific code used to initialize threads, implement critical-sections, perform context-switching, and start the kernel. Most of the time spent in this article focuses on the code found here.

Summarizing the above, these modules provide the following list of functionality:

```
- Thread stack initialization
- Kernel startup and first thread entry
- Context switch and SWI
- Kernel timers
- Critical Sections
.
```

The implementation of each of these pieces will be analyzed in detail in the sections that follow.

Thread Stack Initialization

Before a thread can be used, its stack must first be initialized to its default state. This default state ensures that when the thread is scheduled for the first time and its context restored, that it will cause the CPU to jump to the user's specified entry-point function.

All of the platform independent thread setup is handled by the generic kernel code. However, since every CPU architecture has its own register set, and stacks different information as part of an interrupt/exception, we have to implement this thread setup code for each platform we want the kernel to support (Combination of Architecture + Variant + Toolchain).

In the ARM Cortex-M0 architecture, the stack frame consists of the following information:

a) Exception Stack Frame

Contains the 8 registers which the ARM Cortex-M0 CPU automatically pushes to the stack when entering an exception. The following registers are included (in stack'd order):

```
[ XPSR ] <-- Highest address in context
[ PC   ]
```

```
[ LR  ]
[ R12 ]
[ R3  ]
[ R2  ]
[ R1  ]
[ R0  ]
```

XPSR – This is the CPU's status register. We need to set this to 0x01000000 (the "T" bit), which indicates that the CPU is executing in "thumb" mode. Note that ARMv6m and ARMv7m processors only run thumb2 instructions, so an exception is liable to occur if this bit ever gets cleared.

PC – Program Counter. This should be set with the initial entry point (function pointer) for that the user wishes to start executing with this thread.

LR - The base link register. Normally, this register contains the return address of the calling function, which is where the CPU jumps when a function returns. However, our threads generally don't return (and if they do, they're placed into the stop state). As a result we can leave this as 0.

The other registers in the stack frame are generic working registers, and have no special meaning, with the exception that R0 will hold the user's argument value passed into the entrypoint.

b) Complimentary CPU Register Context

```
[ R11 ]
...
[ R4  ] <-- Lowest address in context
```

These are the other general-purpose CPU registers that need to be backed up/ restored on a context switch, but aren't stacked by default on a Cortex-M0 exception. If there were any additional hardware registers to back up, then we'd also have to include them in this part of the context as well.

As a result, these registers all need to be manually pushed to the stack on stack creation, and will need to be explicitly pushed and pop as part of a normal context switch.

With this default exception state in mind, the following code is used to initialize a thread's stack for a Cortex-M0.

```
void ThreadPort::InitStack(Thread *pclThread_)
{
    K_ULONG *pulStack;
    K_ULONG *pulTemp;
    K_ULONG ulAddr;
    K_USHORT i;

    // Get the entrypoint for the thread
    ulAddr = (K_ULONG)(pclThread_>m_pfEntryPoint);

    // Get the top-of-stack pointer for the thread
    pulStack = (K_ULONG*)pclThread_>m_pwStackTop;

    // Initialize the stack to all FF's to aid in stack depth checking
    pulTemp = (K_ULONG*)pclThread_>m_pwStack;
    for (i = 0; i < pclThread_>m_usStackSize / sizeof(K_ULONG); i++)
    {
        pulTemp[i] = 0xFFFFFFFF;
    }

    PUSH_TO_STACK(pulStack, 0); // Apply one word of padding

    //-- Simulated Exception Stack Frame --
    PUSH_TO_STACK(pulStack, 0x01000000); // XPSR;set "T" bit for thumb-mode
    PUSH_TO_STACK(pulStack, ulAddr); // PC
    PUSH_TO_STACK(pulStack, 0); // LR
    PUSH_TO_STACK(pulStack, 0x12);
    PUSH_TO_STACK(pulStack, 0x3);
    PUSH_TO_STACK(pulStack, 0x2);
    PUSH_TO_STACK(pulStack, 0x1);
    PUSH_TO_STACK(pulStack, (K_ULONG)pclThread_>m_pvArg); // R0 = argument

    //-- Simulated Manually-Stacked Registers --
    PUSH_TO_STACK(pulStack, 0x11);
    PUSH_TO_STACK(pulStack, 0x10);
    PUSH_TO_STACK(pulStack, 0x09);
    PUSH_TO_STACK(pulStack, 0x08);
    PUSH_TO_STACK(pulStack, 0x07);
    PUSH_TO_STACK(pulStack, 0x06);
    PUSH_TO_STACK(pulStack, 0x05);
```

```

    PUSH_TO_STACK(pulStack, 0x04);
    pulStack++;

    pclThread->m_pwStackTop = pulStack;
}

```

Kernel Startup

The same general process applies to starting the kernel on an ARM Cortex-M0 as on other platforms. Here, we initialize and start the platform specific timer and software-interrupt modules, find the first thread to run, and then jump to that first thread.

Now, to perform that last step, we have two options:

1) Simulate a return from an exception manually to start the first thread, or.. 2) Use a software interrupt to trigger the first "Context Restore/Return from Interrupt"

For 1), we basically have to restore the whole stack manually, not relying on the CPU to do any of this for us. That's certainly doable, but not all Cortex parts support this (other members of the family support privileged modes, etc.). That, and the code required to do this is generally more complex due to all of the exception-state simulation. So, we will opt for the second option instead.

To implement a software to start our first thread, we will use the SVC instruction to generate an exception. From that exception, we can then restore the context from our first thread, set the CPU up to use the right "process" stack, and return-from-exception back to our first thread. We'll explore the code for that later.

But, before we can call the SVC exception, we're going to do a couple of things.

First, we're going to reset the default MSP stack pointer to its original top-of-stack value. The rationale here is that we no longer care about the data on the MSP stack, since calling the SVC instruction triggers a chain of events from which we never return. The MSP is also used by all exception-handling, so regaining a few words of stack here can be useful. We'll also enable all maskable exceptions at this point, since this code results in the kernel being started with the CPU executing the RTOS threads, at which point a user would expect interrupts to be enabled.

Note, the default stack pointer location is stored at address 0x00000000 on all ARM Cortex M0 parts. That explains the code below...

```

void ThreadPort_StartFirstThread( void )
{
    asm(
        " ldr r1, [r0] \n" // Reset the MSP to the default base address
        " msr msp, r1 \n"
        " cpsie i \n"      // Enable interrupts
        " svc 0 \n"        // Jump to SVC Call
    );
}

```

First Thread Entry

This handler has the job of taking the first thread object's stack, and restoring the default state data in a way that ensures that the thread starts executing when returning from the call.

We also keep in mind that there's an 8-byte offset from the beginning of the thread object to the location of the thread stack pointer. This offset is a result of the thread object inheriting from the linked-list node class, which has 8-bytes of data. This is stored first in the object, before the first element of the class, which is the "stack top" pointer.

The following assembly code shows how the SVC call is implemented in Mark3 for the purpose of starting the first thread.

```

get_thread_stack:
; Get the stack pointer for the current thread
ldr r0, g_pstCurrent
ldr r1, [r0]
add r1, #8
ldr r2, [r1]          ; r2 contains the current stack-top

load_manually_placed_context_r11_r8:
; Handle the bottom 32-bytes of the stack frame
; Start with r11-r8, because only r0-r7 can be used
; with ldmbia on CM0.
add r2, #16
ldmbia r2!, {r4-r7}

```

```

    mov r11, r7
    mov r10, r6
    mov r9, r5
    mov r8, r4

set_psp:
    ; Since r2 is coincidentally back to where the stack pointer should be,
    ; Set the program stack pointer such that returning from the exception handler
    msr psp, r2

load_manually_placed_context_r7_r4:
    ; Get back to the bottom of the manually stacked registers and pop.
    sub r2, #32
    ldmia r2!, {r4-r7} ; Register r4-r11 are restored.

set_thread_and_privilege_modes:
    ; Also modify the control register to force use of thread mode as well
    ; For CM3 forward-compatibility, also set user mode.
    mrs r0, control
    mov r1, #0x03
    orr r0, r1
    control, r0

set_lr:
    ; Set up the link register such that on return, the code operates
    ; in thread mode using the PSP. To do this, we or 0x0D to the value stored
    ; in the lr by the exception hardware EXC_RETURN. Alternately, we could
    ; just force lr to be 0xFFFFFFF0 (we know that's what we want from the
    ; hardware, anyway)
    mov r0, #0x0D
    mov r1, lr
    orr r0, r1

exit_exception:
    ; Return from the exception handler.
    ; The CPU will automatically unstack R0-R3, R12, PC, LR, and xPSR
    ; for us. If all goes well, our thread will start execution at the
    ; entrypoint, with the us-specified argument.
    bx r0

```

On ARM Cortex parts, there's dedicated hardware that's used primarily to support RTOS (or RTOS-like) functionality. This functionality includes the SysTick timer, and the PendSV Exception. SysTick is used for a tick-based kernel timer, while the PendSV exception is used for performing context switches. In reality, it's a "special SVC" call that's designed to be lower-overhead, in that it isn't mux'd with a bunch of other system or application functionality.

So how do we go about actually implementing a context switch here? There are a lot of different parts involved, but it essentially comes down to 3 steps:

1) Saving the context.

Thread's top-of-stack value is stored, all registers are stacked. We're good to go!

2) Swap threads

We swap the Scheduler's "next" thread with the "current" thread.

3) Restore Context

This is more or less identical to what we did when restoring the first context. Some operations may be optimized for data already stored in registers.

The code used to implement these steps on Cortex-M0 is presented below:

```

void PendSV_Handler(void)
{
    ASM(
        // Thread_SaveContext()
        " ldr r1, CURR_ \n"
        " ldr r1, [r1] \n "
        " mov r3, r1 \n "
        " add r3, #8 \n "

        // Grab the psp and adjust it by 32 based on extra registers we're going
        // to be manually stacking.
        " mrs r2, psp \n "
    )
}

```

```

" sub r2, #32 \n "

// While we're here, store the new top-of-stack value
" str r2, [r3] \n "

// And, while r2 is at the bottom of the stack frame, stack r7-r4
" stmia r2!, {r4-r7} \n "

// Stack r11-r8
" mov r7, r11 \n "
" mov r6, r10 \n "
" mov r5, r9 \n "
" mov r4, r8 \n "
" stmia r2!, {r4-r7} \n "

// Equivalent of Thread_Swap() - performs g_pstCurrent = g_pstNext
" ldr r1, CURR_ \n"
" ldr r0, NEXT_ \n"
" ldr r0, [r0] \n"
" str r0, [r1] \n"

// Thread_RestoreContext()
// Get the pointer to the next thread's stack
" add r0, #8 \n "
" ldr r2, [r0] \n "

// Stack pointer is in r2, start loading registers from
// the "manually-stacked" set
// Start with r11-r8, since these can't be accessed directly.
" add r2, #16 \n "
" ldmbia r2!, {r4-r7} \n "
" mov r11, r7 \n "
" mov r10, r6 \n "
" mov r9, r5 \n "
" mov r8, r4 \n "

// After subbing R2 #16 manually, and #16 through ldmbia, our PSP is where it
// needs to be when we return from the exception handler
" msr psp, r2 \n "

// Pop manually-stacked R4-R7
" sub r2, #32 \n "
" ldmbia r2!, {r4-r7} \n "

// lr contains the proper EXC_RETURN value
// we're done with the exception, so return back to newly-chosen thread
" bx lr \n "
" nop \n "

// Must be 4-byte aligned.
" NEXT_: .word g_pstNext \n"
" CURR_: .word g_pstCurrent \n"
);
}

```

Kernel Timers

ARM Cortex-M series microcontrollers each contain a SysTick timer, which was designed to facilitate a fixed-interval RTOS timer-tick. This timer is a precise 24-bit down-count timer, run at the main CPU clock frequency, that can be programmed to trigger an exception when the timer expires. The handler for this exception can thus be used to drive software timers throughout the system on a fixed interval.

Unfortunately, this hardware is extremely simple, and does not offer the flexibility of other timer hardware commonly implemented by MCU vendors - specifically a suitable timer prescaler that can be used to generate efficient, long-counting intervals. As a result, while the "generic" port of Mark3 for Cortex-M0 leverages the common SysTick timer interface, it only supports the tick-based version of the kernel's timer (note that specific Cortex-M0 ports such as the Atmel SAMD20 do have tickless timers).

Setting up a tick-based [KernelTimer](#) class to use the SysTick timer is, however, extremely easy, as is illustrated below:

```

void KernelTimer::Start(void)
{
    SysTick_Config(PORT_SYSTEM_FREQ / 1000); // 1KHz fixed clock...
    NVIC_EnableIRQ(SysTick_IRQn);
}

```

In [this](#) instance, the call to SysTick_Config() generates a 1kHz system-tick signal, and the NVIC_EnableIRQ() call ensures that a SysTick exception is generated for each tick. All other functions in the Cortex version of the [KernelTimer](#) class are essentially stubbed out (see the source for more details).

Note that the functions used in this call are part of the ARM Cortex Microcontroller Software Interface Standard (cmsis), and are supplied by all parts vendors selling Cortex hardware. This greatly simplifies the design of our port-code, since we can be reasonably assured that these APIs will work the same on all devices.

The handler code called when a SysTick exception occurs is basically the same as on other platforms (such as AVR), except that we explicitly clear the "exception pending" bit before returning. This is implemented in the following code:

```
\code{.cpp}
void SysTick_Handler(void)
{
    #if KERNEL_USE_TIMERS
        TimerScheduler::Process();
    #endif
    #if KERNEL_USE_QUANTUM
        Quantum::UpdateTimer();
    #endif

    // Clear the systick interrupt pending bit.
    SCB->ICSR |= SCB_ICSR_PENDSTCLR_Msk;
}
```

Critical Sections

A "critical section" is a block of code whose execution cannot be interrupted by means of context switches or an interrupt. In a traditional single-core operating system, it is typically implemented as a block of code where the interrupts are disabled - this is also the approach taken by Mark3. Given that every CPU has its own means of disabling/enabling interrupts, the implementation of the critical section APIs is also non-portable.

In the Cortex-M0 port, we implement the two critical section APIs ([CS_ENTER\(\)](#) and [CS_EXIT\(\)](#)) as function-like macros containing inline assembly. All uses of these calls are called in pairs within a function and must take place at the same level-of-scope. Also, as nesting may occur (critical section within a critical section), this must be taken into account in the code.

In general, [CS_ENTER\(\)](#) performs the following tasks:

- Cache the current interrupt-enabled state within a local variable in the thread's state
- Disable interrupts
- .

Conversely, [CS_EXIT\(\)](#) performs the following tasks:

- Read the original interrupt-enabled state from the cached value
- Restore interrupts to the original value
- .

On Cortex-M series microcontrollers, the PRIMASK special register contains a single status bit which can be used to enable/disable all maskable interrupts at once. This register can be read directly to examine or modify its state. For convenience, ARMv6m provides two instructions to enable/disable interrupts

- cpsid (disable interrupts) and cpsie (enable interrupts). Mark3 Implements these steps according to the following code:

```
//-----
#define CS_ENTER() \
{ \
    K_ULONG __ulRegState; \
    asm ( \
        " mrs r0, PRIMASK \n" \
        " mov %[STATUS], r0 \n" \
        " cpsid i \n" \
        : [STATUS] "=r" (__ulRegState) \
        ); \
}

//-----
#define CS_EXIT() \
asm ( \
    " mov r0, %[STATUS] \n" \
    " msr primask, r0 \n" \
    )
```

```
    : \
    : [STATUS] "r" (__ulRegState) \
    ); \
}
```

Summary

In this section we have investigated how the main non-portable areas of the Mark3 RTOS are implemented on a Cortex-M0 microcontroller. Mark3 leverages all of the hardware blocks designed to enable RTOS functionality on ARM Cortex-M series microcontrollers: the SVC call provides the mechanism by which we start the kernel, the PendSV exception provides the necessary software interrupt, and the SysTick timer provides an RTOS tick. As a result, Mark3 is a perfect fit for these devices - and as a result of this approach, the same RTOS port code should work with little to no modification on all ARM Cortex-M parts.

We have discussed what functionality in the RTOS is not portable, and what interfaces must be implemented in order to complete a fully-functional port. The five specific areas which are non-portable (stack initialization, kernel startup/entry, kernel timers, context switching, and critical sections) have been discussed in detail, with the platform-specific source provided as a practical reference to ARM-specific OS features, as well as Mark3's porting infrastructure. From this example (and the accompanying source), it should be possible for an experienced developers to create a port Mark3 to other microcontroller targets.

Chapter 11

Build System

In addition to providing a complete RTOS kernel with a variety of middleware, tests, and example code, Mark3 also provides a robust architecture to efficiently build these components.

The build system – including its design and use, are discussed in the following sections.

11.1 Introduction

As developers, we spend an awful lot of time talking about how our source code is written, but devote very little energy to what happens to the code after it's been written... aside from producing running executables. When I refer to “building better software”, I’m not talking about writing code – I’m talking about the technologies and processes that can be applied to manipulate source into a variety of products, including libraries, applications, tests, documentation, and performance data.

For a lot of developers – embedded or otherwise – a typical build process might look something like this:

Open the IDE, load a project and click “build”. Sometime later, check the output window and look to see that there aren't any red exclamation points to indicate build failure. Browse to your project's output folder to collect your prize: A brand new .elf file containing your new firmware! Click on the arrow to give it a quick run on your dev board, test it for a few minutes, and make sure it seems sane. Pass it off to the manufacturing guys to load it on the line, and move on. Next!

Okay, that's a bit of an exaggeration, but not too far-fetched; and not that much different from standard procedure at places I've worked in the past.

Indeed - I've come across many developers over the years who know about how their software gets built beyond the “black box” that turns their code from text to binaries with the click of the button – and they like it that way. It's entirely understandable, too. Developing from an IDE hides all those messy configuration details, command-line options, symbol definitions and environment variables that would otherwise take away from time spent actively churning out code. We all want to be more productive, of course, and it takes time to learn to make, or anything specific to an embedded toolchain.

And from a product delivery perspective, binaries are the ultimate work-products from a software team – these are the pieces that drive the microcontrollers, DSPs and CPUs in an embedded system. When its crunch time, try convincing management to back off on release date in order to ensure that documentation gets updated to reflect the as-built nature of a project. Or fix the gaps in test coverage. Or update wikis containing profiling and performance metrics. You get the picture.

But software is a living entity – it's constantly changing as it develops and is refined by individuals and teams. And source code is a medium that carries different information across multiple channels all at once – while one channel contains information about building an application, another contains information on building libraries. Another carries information on testing, and another still provides documentation relevant to consumers of the code. While not as glamorous a role as the “living firmware”, these pieces of critical metadata are absolutely necessary as they ensure that the firmware products maintain a degree of quality, performance, and conformance, and gives a degree of confidence before formal test and release activities take place.

This is especially necessary when developing for an organizations that is accountable for their development and documentation practices (for example, ISO shops), or to shareholders who expect the companies they support with their wallets to apply engineering rigour to their products.

But getting the kind of flexibility required to produce these alternative work products form the “example IDE” is not trivial, and can be difficult to apply consistently from project-to-project/IDE-to-IDE. Automating these test and documentation tasks should be considered mandatory if you care about making the most of your development hours; manually generating and updating documentation, tests, and profiling results wastes time that you could be spending solving the right kinds of problems.

The good news, though, is that using common tools available on any modern OS, you can create frameworks that make these tasks for any project, on any toolchain providing command-line tools. With a bit of make, shell-script, and python, you can automate any number of build processes in a way that yields consistent, reliable results that are transferrable from project to project.

This is the approach taken in the Mark3 project, which integrates build, testing, profiling, documentation and release processes together in order to produce predictable, verifiable, output that can be validated against quality gates prior to formal testing and release. Only code revisions that pass all quality gate can be released. In the following sections, we’ll explore the phased build approach, and how it’s used by the Mark3 project.

11.2 Mark3 Build Process Overview

Building software is by and large a serial process, as outputs from each build step are required in subsequent steps. We start from our source code, scripts, and makefiles, configure our environment, and use our tools to turn the source code from one form to another, leveraging the outputs from each stage in the generation of further work products – whether it be creating binaries, running tests, or packaging artifacts for release.

To simplify the design and illustrate the concepts involved, we can break down these serial process into the following distinct phases:

- Pre-build – Environment configuration, target selection, and header-file staging
- Build – Compiling libraries, and building binaries for applications and tests
- Test + Profiling - Running unit tests, integration tests, profiling code
- Release – Generation of documentation from source code and test results, packaging of build artifacts and headers

Each phase and associated activities are described in detail in the following subsections.

11.2.1 Pre-Build Phase:

Target Selection

Inputs: CPU Architecture, Variant, Toolchain variables Outputs: Environment, makefile configuration

In this phase, we select the runtime environment and configure all environment-specific variables. Specifying environment variables at this phase ensures that when the build scripts are run, the correct makefiles, libraries, binaries, and config files are used when generating outputs. This can also be used to ensure that common build setting are applied to all platform specific binaries, including optimization levels, debug symbols, linker files, and CPU flags.

Staging Headers

Inputs: All files with a .h extension, located in library or binary project /public folders Output: Headers copied to a common staging directory

In this step, header files from all platform libraries are copied to a common staging directory referenced by the build system.

This simplifies makefiles and build scripts, ensuring only a single include directory needs to be specified to gain access to all common platform libraries. This keeps library and application code clean, as relative paths can be

completely avoided. As an added benefit, these headers can later be deployed with the corresponding libraries to customers, giving them access to a set of pre-compiled libraries with APIs, but without providing the source.

11.2.2 Build Phase

Building Libraries

Input: Source code for all common libraries, staged headers Output: Static libraries that can be linked against applications Gate: All mandatory libraries must be built successfully

The project root directory is scanned recursively for directories containing makefiles. When a makefile is found in the root of a subdirectory and a library tag is encountered (in Mark3, this corresponds to the declaration "IS_LIB=1"), the project is built using the library-specific make commands for the platform. Libraries can reference other libraries implicitly, and include headers from the common include directory. Since references are resolved when building executable binary images, the executable projects are responsible for including the dependent libs.

Building Binaries

Input: Source code for individual applications, precompiled libraries, staged headers Output: Executable application and test binaries Gate: All mandatory binaries (applications and tests) must be built successfully

The project root directory is scanned recursively for directories containing makefiles. When a makefile is found in the root of a subdirectory and a binary tag is encountered (in Mark3, this corresponds to the declaration "IS_APP=1"), the project is built using the executable-specific make commands for the platform. Applications can reference all platform and toolchain libraries, and include headers from the common include directory. Care must be taken to ensure that all library dependencies are explicitly specified in the application's makefile's list.

This step will fail if necessary dependencies are not met (i.e. required libraries failed to build in a prior step).

Static Analysis:

Input: Source code for libraries/binaries Output: Static source analysis output Gate: N/A

Static analysis tools such as clang, klocwork, and lint can be run on the source to ensure that there are no critical or catastrophic problems (null pointer exceptions, variables used before initialization, incorrect argument usage, etc.) that wouldn't necessarily be caught at compile-time. Since tool availability and configurability varies, this isn't something that is enforced in the Mark3 builds. A user may opt to use clang to perform static code analysis on the build, however. The part-specific makefile contains a CLANG environment variable for this purpose.

Potential quality gates could be set up such that a failure during static analysis aborts the rest of the build.

Test + Profiling Sanity Tests

Input: Executable test binaries, CPU simulator/embedded target system Output: Text output indicating test pass/failure status

11.2.3 Test and Profile

Unit Tests

Input: Executable test binaries, CPU simulator/embedded target system Output: Text output indicating test pass/failure status

Code Performance Profiling

Input: Executable test binaries, CPU simulator/embedded target system Output: Text output containing critical code performance metrics

Code Size Profiling

Input: Precompiled static libraries and binaries Output: Text output containing critical code size metrics

11.2.4 Release

Documentation

Input: Library source code and headers, commented with Doxygen tags, Profiling results, Test results Output: Doxygen-generated HTML and PDF documentation

Packaging

Input: Static libraries and application/test binaries, staged headers, compiled documentation Output: Archive (.zip) containing relevant build outputs

Chapter 12

Mark3C - C-language API bindings for the Mark3 Kernel.

Mark3 now includes an optional additional library with C language bindings for all core kernel APIs, known as Mark3C.

This library allows applications to be written in C, while still enjoying all of the benefits of the clean, modular design of the core RTOS kernel.

The C-language Mark3C APIs map directly to their Mark3 counterparts using a simple set of conventions, documented below. As a result, explicit API documentation for Mark3C is not necessary, as the functions map 1-1 to their C++ counterparts.

12.1 API Conventions

1) Static Methods:

<code><ClassName>::<MethodName>()</code>	Becomes	<code><ClassName>_<MethodhName>()</code>
i.e. <code>Kernel::Start()</code>	Becomes	<code>Kernel_Start()</code>

2) [Kernel](#) Object Methods:

In short, any class instance is represented using an object handle, and is always passed into the relevant APIs as the first argument. Further, any method that returns a pointer to an object in the C++ implementation now returns a handle to that object.

<code><Object>.<MethodName>(<args>)</code>	Becomes	<code><ClassName>_<MethodhName>(<ObjectHandle>, <args>)</code>
i.e. <code>clAppThread.Start()</code>	Becomes	<code>Thread_Start(hAppThread)</code>

3) Overloaded Methods:

a) Methods overloaded with a Timeout parameter:

<code><Object>.<MethodName>(<args>)</code>	Becomes	<code><ClassName>_Timed<MethodhName>(<ObjectHandle>, <args>)</code>
i.e. <code>clSemaphore.Wait(1000)</code>	Becomes	<code>Semaphore_Wait(hSemaphore, 1000)</code>

b) Methods overloaded based on number of arguments:

<code><Object>.<MethodName>()</code>	Becomes	<code><ClassName>_<MethodhName>(<ObjectHandle>)</code>
<code><Object>.<MethodName>(<arg1>)</code>	Becomes	<code><ClassName>_<MethodhName>1(<ObjectHandle>, <arg1>)</code>
<code><Object>.<MethodName>(<arg1>, <arg2>)</code>	Becomes	<code><ClassName>_<MethodhName>2(<ObjectHandle>, <arg1>, <arg2>)</code>

<ClassName>::<MethodName>()	Becomes	<ClassName>_<MethodName>(<ObjectHandle>)
<ClassName>::<MethodName>(<arg1>)	Becomes	<ClassName>_<MethodName>1(<ObjectHandle>, <arg1>)
<ClassName>::<MethodName>(<arg1>, <arg2>)	Becomes	<ClassName>_<MethodName>2(<ObjectHandle>, <arg1>, <arg2>)

c) Methods overloaded base on parameter types:

<Object>.<MethodName>(<arg type_a>)	Becomes	<ClassName>_<MethodName><type_a>(<ObjectHandle>, <arg type_a>)
<Object>.<MethodName>(<arg type_b>)	Becomes	<ClassName>_<MethodName><type_b>(<ObjectHandle>, <arg type_b>)
<ClassName>::<MethodName>(<arg type_a>)	Becomes	<ClassName>_<MethodName><type_a>(<arg type a>)
<ClassName>::<MethodName>(<arg type_b>)	Becomes	<ClassName>_<MethodName><type_b>(<arg type b>)

d) Allocate-once memory allocation APIs

AutoAlloc::New<ObjectName>	Becomes	Alloc_<ObjectName>
AutoAlloc::Allocate(uint16_t u16Size_)	Becomes	AutoAlloc(uint16_t u16Size_)

12.2 Allocating Objects

Aside from the API name translations, the object allocation scheme is the major different between Mark3C and Mark3. Instead of instantiating objects of the various kernel types, kernel objects must be declared using Declaration macros, which serve the purpose of reserving memory for the kernel object, and provide an opaque handle to that object memory. This is the case for statically-allocated objects, and objects allocated on the stack.

Example: Declaring a thread

```
#include "mark3c.h"

// Statically-allocated
DECLARE_THREAD(hMyThread1);
...

// On stack
int main(void)
{
    DECLARE_THREAD(hMyThread2);
    ...
}
```

Where:

hMyThread1 - is a handle to a statically-allocated thread
hMyThread2 - is a handle to a thread allocated from the main stack.

Alternatively, the AutoAlloc APIs can be used to dynamically allocate objects, as demonstrated in the following example.

```
void Allocate_Example(void)
{
    Thread_t hMyThread = AutoAlloc_Thread();

    Thread_Init(hMyThread, awMyStack, sizeof(awMyStack), 1, MyFunction, 0);
}
```

Note that the relevant kernel-object Init() function *must* be called prior to using any kernel object, whether or not they have been allocated statically, or dynamically.

12.3 Drivers in Mark3C

Because the Mark3 driver framework makes extensive use of inheritance and virtual functions in C++, it is difficult to wrap for use with C. In addition, all derived drivers types would still need to have their custom interfaces wrapped

with C-language bindings in order to be accessible from C, which is cumbersome and inelegant, and duplicates large portions of code. As a result, it's probably less work to write a Mark3C specific driver module with a similar interface to Mark3, on which drivers can be ported where necessary, or implemented directly on for efficiency. The APIs presented in [driver3c.h](#) provide such an interface for use in Mark3c.

Chapter 13

Release Notes

13.1 R4 Release

- New: C-language bindings for Mark3 kernel (mark3c library)
- New: Support for ARM Cortex-M3 and Cortex-M4 (floating point) targets
- New: Support for Atmel AVR atmega2560 and arduino pro mega
- New: Full-featured, lightweight heap implementation
- New: [Mailbox](#) IPC class
- New: Notification object class
- New: lightweight tracelogger/instrumentation implementation (buffalogger), with sample parser
- New: High-performance AVR Software UART implementation
- New: Allocate-once "AutoAlloc" memory allocator
- New: Fixed-time blocking/unblocking operations added to ThreadList/Blocking class
- Placement-new supported for all kernel objects
- [Scheduler](#) now supports up to 1024 levels of thread priority, up from 8 (configurable at build-time)
- [Kernel](#) now uses stdint.h types for standard integers (instead of K_CHAR, K_ULONG, etc.)
- Greatly expanded documentation, with many new examples covering all key kernel features
- Expanded unit test coverage on AVR
- Updated build system and scripts for easier kernel configuration
- Updated builds to only attempt to build tests for supported platforms

13.2 R3 Release

- New: Added support for MSP430 microcontrollers
- New: Added [Kernel](#) Idle-Function hook to eliminate the need for a dedicated idle-thread (where supported)
- New: Support for kernel-aware simulation and testing via fIAVR AVR simulator
- Updated AVR driver selection
- General bugfixes and maintenance
- Expanded documentation and test coverage

13.3 R2

- Experimental release, using a "kernel transaction queue" for serializing kernel calls
- Works as a proof-of-concept, but abandoned due to overhead of the transaction mechanism in the general case.

13.4 R1 - 2nd Release

- New: Added support for ARM Cortex-M0 targets
- New: Added support for various AVR targets
- New: Timers now support a "tolerance" parameter for grouping timers with close expiry times
- Expanded scripts and automation used in build/test
- Updated and expanded graphics APIs
- Large number of bugfixes

13.5 R1 - 1st Release

- Initial release, with support for AVR microcontrollers

Chapter 14

Profiling Results

The following profiling results were obtained using an ATmega328p @ 16MHz.

The test cases are designed to make use of the kernel profiler, which accurately measures the performance of the fundamental system APIs, in order to provide information for user comparison, as well as to ensure that regressions are not being introduced into the system.

14.1 Date Performed

Tue Sep 27 19:52:31 EDT 2016

14.2 Compiler Information

The kernel and test code used in these results were built using the following compiler:

```
Using built-in specs.
COLLECT_GCC=avr-gcc
COLLECT_LTO_WRAPPER=/usr/lib/gcc/avr/4.8.2/lto-wrapper
Target: avr
Configured with: ../src/configure -v --enable-languages=c,c++ --prefix=/usr/lib --infodir=/usr/share/info --mandir=/usr/share/man --bindir=/usr/bin --libexecdir=/usr/lib --libdir=/usr/lib --enable-shared --with-system-zlib --enable-long-long --enable-nls --without-included-gettext --disable-libssp --build=x86_64-linux-gnu --host=x86_64-linux-gnu --target=avr
Thread model: single
gcc version 4.8.2 (GCC)
```

14.3 Profiling Results

```
- Semaphore Initialization: 40 cycles (averaged over 42 iterations)
- Semaphore Post (uncontested): 104 cycles (averaged over 42 iterations)
- Semaphore Pend (uncontested): 57 cycles (averaged over 42 iterations)
- Semaphore Flyback Time (Contested Pend): 1624 cycles (averaged over 42 iterations)
- Mutex Init: 208 cycles (averaged over 43 iterations)
- Mutex Claim: 208 cycles (averaged over 43 iterations)
- Mutex Release: 112 cycles (averaged over 42 iterations)
- Thread Initialize: 8304 cycles (averaged over 42 iterations)
- Thread Start: 792 cycles (averaged over 42 iterations)
- Context Switch: 200 cycles (averaged over 42 iterations)
- Thread Schedule: 64 cycles (averaged over 42 iterations)
```

Chapter 15

Code Size Profiling

The following report details the size of each module compiled into the kernel.

The size of each component is dependent on the flags specified in [mark3cfg.h](#) at compile time. Note that these sizes represent the maximum size of each module before dead code elimination and any additional link-time optimization, and represent the maximum possible size that any module can take.

The results below are for profiling on Atmel AVR atmega328p-based targets using gcc. Results are not necessarily indicative of relative or absolute performance on other platforms or toolchains.

- Atmel AVR - Kernel Timer Implementation..... : 302 Bytes
- Atmel AVR - Profiling Timer Implementation..... : 216 Bytes

```

Mark3 Kernel Size Summary:

```

- Kernel : 3054 Bytes
- Synchronization Objects : 2350 Bytes
- Port : 2758 Bytes
- Features : 2037 Bytes
- Total Size : 10199 Bytes

```

Chapter 16

Hierarchical Index

16.1 Class Hierarchy

This inheritance list is sorted roughly, but not completely, alphabetically:

BlockingObject	87
EventFlag	99
Mutex	136
Notify	140
Semaphore	152
DriverList	97
FakeThread_t	102
GlobalMessagePool	103
Kernel	104
KernelAware	110
KernelAwareData_t	114
KernelSWI	115
KernelTimer	117
LinkList	120
CircularLinkList	88
ThreadList	164
DoubleLinkList	93
TimerList	173
LinkListNode	121
Driver	94
DevNull	90
Message	130
Thread	155
Timer	168
Mailbox	123
MessagePool	133
MessageQueue	134
PriorityMap	142
Profiler	143
ProfileTimer	144
Quantum	147
Scheduler	148
ThreadPort	167
TimerScheduler	175

Chapter 17

Class Index

17.1 Class List

Here are the classes, structs, unions and interfaces with brief descriptions:

BlockingObject	Class implementing thread-blocking primitives	87
CircularLinkedList	Circular-linked-list data type, inherited from the base LinkedList type	88
DevNull	This class implements the "default" driver (/dev/null)	90
DoubleLinkedList	Doubly-linked-list data type, inherited from the base LinkedList type	93
Driver	Base device-driver class used in hardware abstraction	94
DriverList	List of Driver objects used to keep track of all device drivers in the system	97
EventFlag	Blocking object, similar to a semaphore or mutex, commonly used for synchronizing thread execution based on events occurring within the system	99
FakeThread_t	If the kernel is set up to use an idle function instead of an idle thread, we use a placeholder data structure to "simulate" the effect of having an idle thread in the system	102
GlobalMessagePool	Implements a list of message objects shared between all threads	103
Kernel	Class that encapsulates all of the kernel startup functions	104
KernelAware	The KernelAware class	110
KernelAwareData_t	This structure is used to communicate between the kernel and a kernel-aware host	114
KernelSWI	Class providing the software-interrupt required for context-switching in the kernel	115
KernelTimer	Hardware timer interface, used by all scheduling/timer subsystems	117
LinkedList	Abstract-data-type from which all other linked-lists are derived	120
LinkedListNode	Basic linked-list node data structure	121
Mailbox	Implements an IPC mechanism based on envelopes containing data of a fixed size (configured at initialization) that reside within a buffer of memory provided by the user	123

Message	Class to provide message-based IPC services in the kernel	130
MessagePool	Implements a list of message objects	133
MessageQueue	List of messages, used as the channel for sending and receiving messages between threads .	134
Mutex	Mutual-exclusion locks, based on BlockingObject	136
Notify	Blocking object type, that allows one or more threads to wait for an event to occur before resuming operation	140
PriorityMap	The PriorityMap class	142
Profiler	System profiling timer interface	143
ProfileTimer	Profiling timer	144
Quantum	Static-class used to implement Thread quantum functionality, which is a key part of round-robin scheduling	147
Scheduler	Priority-based round-robin Thread scheduling, using ThreadLists for housekeeping	148
Semaphore	Binary & Counting semaphores, based on BlockingObject base class	152
Thread	Object providing fundamental multitasking support in the kernel	155
ThreadList	This class is used for building thread-management facilities, such as schedulers, and blocking objects	164
ThreadPort	Class defining the architecture specific functions required by the kernel	167
Timer	Kernel-managed software timers	168
TimerList	TimerList class - a doubly-linked-list of timer objects	173
TimerScheduler	"Static" Class used to interface a global TimerList with the rest of the kernel	175

Chapter 18

File Index

18.1 File List

Here is a list of all documented files with brief descriptions:

/home/moslevin/mark3-source/embedded/kernel/ atomic.cpp	
Basic Atomic Operations	177
/home/moslevin/mark3-source/embedded/kernel/ autoalloc.cpp	
Automatic memory allocation for kernel objects	179
/home/moslevin/mark3-source/embedded/kernel/ blocking.cpp	
Implementation of base class for blocking objects	181
/home/moslevin/mark3-source/embedded/kernel/ driver.cpp	
Device driver/hardware abstraction layer	201
/home/moslevin/mark3-source/embedded/kernel/ eventflag.cpp	
Event Flag Blocking Object/IPC-Object implementation	203
/home/moslevin/mark3-source/embedded/kernel/ kernel.cpp	
Kernel initialization and startup code	208
/home/moslevin/mark3-source/embedded/kernel/ kernelaware.cpp	
Kernel aware simulation support	210
/home/moslevin/mark3-source/embedded/kernel/ ksemaphore.cpp	
Semaphore Blocking-Object Implemenation	212
/home/moslevin/mark3-source/embedded/kernel/ ll.cpp	
Core Linked-List implementation, from which all kernel objects are derived	216
/home/moslevin/mark3-source/embedded/kernel/ mailbox.cpp	
Mailbox + Envelope IPC mechanism	218
/home/moslevin/mark3-source/embedded/kernel/ message.cpp	
Inter-thread communications via message passing	222
/home/moslevin/mark3-source/embedded/kernel/ mutex.cpp	
Mutual-exclusion object	225
/home/moslevin/mark3-source/embedded/kernel/ notify.cpp	
Lightweight thread notification - blocking object	228
/home/moslevin/mark3-source/embedded/kernel/ priomap.cpp	
Priority map data structure	231
/home/moslevin/mark3-source/embedded/kernel/ profile.cpp	
Code profiling utilities	232
/home/moslevin/mark3-source/embedded/kernel/ quantum.cpp	
Thread Quantum Implementation for Round-Robin Scheduling	289
/home/moslevin/mark3-source/embedded/kernel/ scheduler.cpp	
Strict-Priority + Round-Robin thread scheduler implementation	291
/home/moslevin/mark3-source/embedded/kernel/ thread.cpp	
Platform-Independent thread class Definition	293
/home/moslevin/mark3-source/embedded/kernel/ threadlist.cpp	
Thread linked-list definitions	299

/home/moslevin/mark3-source/embedded/kernel/timer.cpp	
Timer implementations	301
/home/moslevin/mark3-source/embedded/kernel/timerlist.cpp	
Implements timer list processing algorithms, responsible for all timer tick and expiry logic . . .	303
/home/moslevin/mark3-source/embedded/kernel/tracebuffer.cpp	
Kernel trace buffer class definition	306
/home/moslevin/mark3-source/embedded/kernel/cpu/avr/atmega328p/gcc/kernelprofile.cpp	
ATMega328p Profiling timer implementation	183
/home/moslevin/mark3-source/embedded/kernel/cpu/avr/atmega328p/gcc/kernelswi.cpp	
Kernel Software interrupt implementation for ATMega328p	184
/home/moslevin/mark3-source/embedded/kernel/cpu/avr/atmega328p/gcc/kerneltimer.cpp	
Kernel Timer Implementation for ATMega328p	185
/home/moslevin/mark3-source/embedded/kernel/cpu/avr/atmega328p/gcc/threadport.cpp

Chapter 19

Class Documentation

19.1 BlockingObject Class Reference

Class implementing thread-blocking primitives.

```
#include <blocking.h>
```

Inheritance diagram for BlockingObject:

Protected Member Functions

- void **Block** (Thread *pclThread_)
Block.
- void **BlockPriority** (Thread *pclThread_)
BlockPriority.
- void **UnBlock** (Thread *pclThread_)
UnBlock.

Protected Attributes

- ThreadList m_clBlockList
ThreadList which is used to hold the list of threads blocked on a given object.

19.1.1 Detailed Description

Class implementing thread-blocking primitives.

used for implementing things like semaphores, mutexes, message queues, or anything else that could cause a thread to suspend execution on some external stimulus.

Definition at line 65 of file [blocking.h](#).

19.1.2 Member Function Documentation

19.1.2.1 void BlockingObject::Block (Thread * *pclThread_*) [protected]

Block.

Blocks a thread on this object. This is the fundamental operation performed by any sort of blocking operation in the operating system. All semaphores/mutexes/sleeping/messaging/etc ends up going through the blocking code at some point as part of the code that manages a transition from an "active" or "waiting" thread to a "blocked" thread.

The steps involved in blocking a thread (which are performed in the function itself) are as follows;

1) Remove the specified thread from the current owner's list (which is likely one of the scheduler's thread lists) 2) Add the thread to this object's thread list 3) Setting the thread's "current thread-list" point to reference this object's threadlist.

Parameters

<i>pclThread_</i>	Pointer to the thread object that will be blocked.
-------------------	--

Definition at line 41 of file [blocking.cpp](#).

19.1.2.2 void BlockingObject::BlockPriority (Thread * *pclThread_*) [protected]

BlockPriority.

Same as [Block\(\)](#), but ensures that threads are added to the block-list in priority-order, which optimizes the unblock procedure.

Parameters

<i>pclThread_</i>	Pointer to the Thread to Block.
-------------------	---

Definition at line 57 of file [blocking.cpp](#).

19.1.2.3 void BlockingObject::UnBlock (Thread * *pclThread_*) [protected]

UnBlock.

Unblock a thread that is already blocked on this object, returning it to the "ready" state by performing the following steps:

Parameters

<i>pclThread_</i>	Pointer to the thread to unblock.
-------------------	-----------------------------------

1) Removing the thread from this object's threadlist 2) Restoring the thread to its "original" owner's list

Definition at line 73 of file [blocking.cpp](#).

The documentation for this class was generated from the following files:

- [/home/moslevin/mark3-source/embedded/kernel/public/blocking.h](#)
- [/home/moslevin/mark3-source/embedded/kernel/blocking.cpp](#)

19.2 CircularLinkedList Class Reference

Circular-linked-list data type, inherited from the base [LinkList](#) type.

```
#include <ll.h>
```

Inheritance diagram for CircularLinkedList:

Public Member Functions

- void [Add](#) ([LinkListNode](#) *node_)
Add the linked list node to this linked list.
- void [Remove](#) ([LinkListNode](#) *node_)
Remove.
- void [PivotForward](#) ()
PivotForward.
- void [PivotBackward](#) ()
PivotBackward.
- void [InsertNodeBefore](#) ([LinkListNode](#) *node_, [LinkListNode](#) *insert_)
InsertNodeBefore.

Additional Inherited Members

19.2.1 Detailed Description

Circular-linked-list data type, inherited from the base [LinkList](#) type.

Definition at line 187 of file [ll.h](#).

19.2.2 Member Function Documentation

19.2.2.1 void CircularLinkedList::Add (LinkListNode * node_)

Add the linked list node to this linked list.

Parameters

<i>node_</i>	Pointer to the node to add
--------------	----------------------------

Definition at line 98 of file [ll.cpp](#).

19.2.2.2 void CircularLinkedList::InsertNodeBefore (LinkListNode * node_, LinkListNode * insert_)

InsertNodeBefore.

Insert a linked-list node into the list before the specified insertion point.

Parameters

<i>node_</i>	Node to insert into the list
<i>insert_</i>	Insert point.

Definition at line 172 of file [ll.cpp](#).

19.2.2.3 void CircularLinkedList::PivotBackward ()

PivotBackward.

Pivot the head of the circularly linked list backward (Head = Head->prev, Tail = Tail->prev)

Definition at line 163 of file [ll.cpp](#).

19.2.2.4 void CircularLinkedList::PivotForward ()

PivotForward.

Pivot the head of the circularly linked list forward (Head = Head->next, Tail = Tail->next)

Definition at line 154 of file [ll.cpp](#).

19.2.2.5 void CircularLinkedList::Remove (LinkListNode * node_)

Remove.

Add the linked list node to this linked list

Parameters

<i>node_</i>	Pointer to the node to remove
--------------	-------------------------------

Definition at line 120 of file [ll.cpp](#).

The documentation for this class was generated from the following files:

- [/home/moslevin/mark3-source/embedded/kernel/public/ll.h](#)
- [/home/moslevin/mark3-source/embedded/kernel/ll.cpp](#)

19.3 DevNull Class Reference

This class implements the "default" driver (/dev/null)

Inheritance diagram for DevNull:

Public Member Functions

- virtual void [Init](#) ()
Init.
- virtual uint8_t [Open](#) ()
Open.
- virtual uint8_t [Close](#) ()
Close.
- virtual uint16_t [Read](#) (uint16_t u16Bytes_, uint8_t *pu8Data_)
Read.

- virtual uint16_t [Write](#) (uint16_t u16Bytes_, uint8_t *pu8Data_)
Write.
- virtual uint16_t [Control](#) (uint16_t u16Event_, void *pvDataIn_, uint16_t u16SizeIn_, void *pvDataOut_
, uint16_t u16SizeOut_)
Control.

Additional Inherited Members

19.3.1 Detailed Description

This class implements the "default" driver (/dev/null)

Definition at line 46 of file [driver.cpp](#).

19.3.2 Member Function Documentation

19.3.2.1 virtual uint8_t DevNull::Close () [inline], [virtual]

Close.

Close a previously-opened device driver.

Returns

Driver-specific return code, 0 = OK, non-0 = error

Implements [Driver](#).

Definition at line 51 of file [driver.cpp](#).

19.3.2.2 virtual uint16_t DevNull::Control (uint16_t u16Event_, void * pvDataIn_, uint16_t u16SizeIn_, void * pvDataOut_, uint16_t u16SizeOut_) [inline], [virtual]

Control.

This is the main entry-point for device-specific io and control operations. This is used for implementing all "side-channel" communications with a device, and any device-specific IO operations that do not conform to the typical POSIX read/write paradigm. use of this function is analogous to the non-POSIX (yet still common) devctl() or ioctl().

Parameters

<i>u16Event_</i>	Code defining the io event (driver-specific)
<i>pvDataIn_</i>	Pointer to the input data
<i>u16SizeIn_</i>	Size of the input data (in bytes)
<i>pvDataOut_</i>	Pointer to the output data
<i>u16SizeOut_</i>	Size of the output data (in bytes)

Returns

Driver-specific return code, 0 = OK, non-0 = error

Implements [Driver](#).

Definition at line 55 of file [driver.cpp](#).

19.3.2.3 `virtual void DevNull::Init () [inline],[virtual]`

Init.

Initialize a driver, must be called prior to use

Implements [Driver](#).

Definition at line 49 of file [driver.cpp](#).

19.3.2.4 `virtual uint8_t DevNull::Open () [inline],[virtual]`

Open.

Open a device driver prior to use.

Returns

Driver-specific return code, 0 = OK, non-0 = error

Implements [Driver](#).

Definition at line 50 of file [driver.cpp](#).

19.3.2.5 `virtual uint16_t DevNull::Read (uint16_t u16Bytes_, uint8_t * pu8Data_) [inline],[virtual]`

Read.

Read a specified number of bytes from the device into a specific buffer. Depending on the driver-specific implementation, this may be a number less than the requested number of bytes read, indicating that there there was less input than desired, or that as a result of buffering, the data may not be available.

Parameters

<i>u16Bytes_</i>	Number of bytes to read (<= size of the buffer)
<i>pu8Data_</i>	Pointer to a data buffer receiving the read data

Returns

Number of bytes actually read

Implements [Driver](#).

Definition at line 52 of file [driver.cpp](#).

19.3.2.6 `virtual uint16_t DevNull::Write (uint16_t u16Bytes_, uint8_t * pu8Data_) [inline],[virtual]`

Write.

Write a payload of data of a given length to the device. Depending on the implementation of the driver, the amount of data written to the device may be less than the requested number of bytes. A result less than the requested size may indicate that the device buffer is full, indicating that the user must retry the write at a later point with the remaining data.

Parameters

<i>u16Bytes_</i>	Number of bytes to write (<= size of the buffer)
------------------	--

<code>pu8Data_</code>	Pointer to a data buffer containing the data to write
-----------------------	---

Returns

Number of bytes actually written

Implements [Driver](#).

Definition at line 53 of file [driver.cpp](#).

19.4 DoubleLinkedList Class Reference

Doubly-linked-list data type, inherited from the base [LinkedList](#) type.

```
#include <ll.h>
```

Inheritance diagram for DoubleLinkedList:

**Public Member Functions**

- [DoubleLinkedList](#) ()
DoubleLinkedList.
- void [Add](#) ([LinkedListNode](#) *node_)
Add.
- void [Remove](#) ([LinkedListNode](#) *node_)
Remove.

Additional Inherited Members

19.4.1 Detailed Description

Doubly-linked-list data type, inherited from the base [LinkedList](#) type.

Definition at line 149 of file [ll.h](#).

19.4.2 Constructor & Destructor Documentation

19.4.2.1 [DoubleLinkedList::DoubleLinkedList](#) () `[inline]`

[DoubleLinkedList](#).

Default constructor - initializes the head/tail nodes to NULL

Definition at line 158 of file [ll.h](#).

19.4.3 Member Function Documentation

19.4.3.1 void DoubleLinkedList::Add (LinkListNode * node_)

Add.

Add the linked list node to this linked list

Parameters

<i>node_</i>	Pointer to the node to add
--------------	----------------------------

Definition at line 47 of file [ll.cpp](#).

19.4.3.2 void DoubleLinkedList::Remove (LinkListNode * node_)

Remove.

Add the linked list node to this linked list

Parameters

<i>node_</i>	Pointer to the node to remove
--------------	-------------------------------

Definition at line 68 of file [ll.cpp](#).

The documentation for this class was generated from the following files:

- [/home/moslevin/mark3-source/embedded/kernel/ll.cpp](#)

19.5 Driver Class Reference

Base device-driver class used in hardware abstraction.

```
#include <driver.h>
```

Inheritance diagram for Driver:

Public Member Functions

- virtual void [Init](#) ()=0
Init.
- virtual uint8_t [Open](#) ()=0
Open.
- virtual uint8_t [Close](#) ()=0
Close.
- virtual uint16_t [Read](#) (uint16_t u16Bytes_, uint8_t *pu8Data_)=0
Read.
- virtual uint16_t [Write](#) (uint16_t u16Bytes_, uint8_t *pu8Data_)=0

Write.

- virtual uint16_t [Control](#) (uint16_t u16Event_, void *pvDataIn_, uint16_t u16SizeIn_, void *pvDataOut__↔, uint16_t u16SizeOut_)=0

Control.

- void [SetName](#) (const char *pcName_)

SetName.

- const char * [GetPath](#) ()

GetPath.

Private Attributes

- const char * [m_pcPath](#)

string pointer that holds the driver path (name)

Additional Inherited Members

19.5.1 Detailed Description

Base device-driver class used in hardware abstraction.

All other device drivers inherit from this class

Definition at line 121 of file [driver.h](#).

19.5.2 Member Function Documentation

19.5.2.1 virtual uint8_t Driver::Close () [pure virtual]

Close.

Close a previously-opened device driver.

Returns

Driver-specific return code, 0 = OK, non-0 = error

Implemented in [DevNull](#).

19.5.2.2 virtual uint16_t Driver::Control (uint16_t u16Event_, void * pvDataIn_, uint16_t u16SizeIn_, void * pvDataOut_, uint16_t u16SizeOut_) [pure virtual]

Control.

This is the main entry-point for device-specific io and control operations. This is used for implementing all "side-channel" communications with a device, and any device-specific IO operations that do not conform to the typical POSIX read/write paradigm. use of this function is analogous to the non-POSIX (yet still common) devctl() or ioctl().

Parameters

<i>u16Event_</i>	Code defining the io event (driver-specific)
<i>pvDataIn_</i>	Pointer to the input data
<i>u16SizeIn_</i>	Size of the input data (in bytes)

<i>pvDataOut_</i>	Pointer to the output data
<i>u16SizeOut_</i>	Size of the output data (in bytes)

Returns

Driver-specific return code, 0 = OK, non-0 = error

Implemented in [DevNull](#).

19.5.2.3 const char* Driver::GetPath () [inline]

GetPath.

Returns a string containing the device path.

Returns

pcName_ Return the string constant representing the device path

Definition at line 221 of file [driver.h](#).

19.5.2.4 virtual void Driver::Init () [pure virtual]

Init.

Initialize a driver, must be called prior to use

Implemented in [DevNull](#).

19.5.2.5 virtual uint8_t Driver::Open () [pure virtual]

Open.

Open a device driver prior to use.

Returns

Driver-specific return code, 0 = OK, non-0 = error

Implemented in [DevNull](#).

19.5.2.6 virtual uint16_t Driver::Read (uint16_t u16Bytes_, uint8_t* pu8Data_) [pure virtual]

Read.

Read a specified number of bytes from the device into a specific buffer. Depending on the driver-specific implementation, this may be a number less than the requested number of bytes read, indicating that there was less input than desired, or that as a result of buffering, the data may not be available.

Parameters

<i>u16Bytes_</i>	Number of bytes to read (<= size of the buffer)
<i>pu8Data_</i>	Pointer to a data buffer receiving the read data

Returns

Number of bytes actually read

Implemented in [DevNull](#).

19.5.2.7 `void Driver::SetName (const char * pcName_) [inline]`

SetName.

Set the path for the driver. Name must be set prior to access (since driver access is name-based).

Parameters

<i>pcName_</i>	String constant containing the device path
----------------	--

Definition at line 213 of file [driver.h](#).

19.5.2.8 `virtual uint16_t Driver::Write (uint16_t u16Bytes_, uint8_t * pu8Data_) [pure virtual]`

Write.

Write a payload of data of a given length to the device. Depending on the implementation of the driver, the amount of data written to the device may be less than the requested number of bytes. A result less than the requested size may indicate that the device buffer is full, indicating that the user must retry the write at a later point with the remaining data.

Parameters

<i>u16Bytes_</i>	Number of bytes to write (<= size of the buffer)
<i>pu8Data_</i>	Pointer to a data buffer containing the data to write

Returns

Number of bytes actually written

Implemented in [DevNull](#).

The documentation for this class was generated from the following file:

- [/home/moslevin/mark3-source/embedded/kernel/public/driver.h](#)

19.6 DriverList Class Reference

List of [Driver](#) objects used to keep track of all device drivers in the system.

```
#include <driver.h>
```

Static Public Member Functions

- static void [Init](#) ()
Init.
- static void [Add](#) ([Driver](#) **pcIDriver_*)
Add.
- static void [Remove](#) ([Driver](#) **pcIDriver_*)
Remove.
- static [Driver](#) * [FindByPath](#) (const char **m_pcPath*)
FindByPath.

Static Private Attributes

- static [DoubleLinkedList](#) [m_clDriverList](#)
LinkedList object used to implementing the driver object management.

19.6.1 Detailed Description

List of [Driver](#) objects used to keep track of all device drivers in the system.

By default, the list contains a single entity, `"/dev/null"`.

Definition at line [232](#) of file [driver.h](#).

19.6.2 Member Function Documentation

19.6.2.1 `static void DriverList::Add (Driver * pciDriver_)` `[inline], [static]`

Add.

Add a [Driver](#) object to the managed global driver-list.

Parameters

<code><i>pciDriver_</i></code>	pointer to the driver object to add to the global driver list.
--------------------------------	--

Examples:

[buffalogger/main.cpp](#).

Definition at line [252](#) of file [driver.h](#).

19.6.2.2 `Driver * DriverList::FindByPath (const char * m_pcPath)` `[static]`

FindByPath.

Look-up a driver in the global driver-list based on its path. In the event that the driver is not found in the list, a pointer to the default `"/dev/null"` object is returned. In this way, unimplemented drivers are automatically stubbed out.

Definition at line [104](#) of file [driver.cpp](#).

19.6.2.3 `void DriverList::Init ()` `[static]`

Init.

Initialize the list of drivers. Must be called prior to using the device driver library.

Definition at line [95](#) of file [driver.cpp](#).

19.6.2.4 `static void DriverList::Remove (Driver * pciDriver_)` `[inline], [static]`

Remove.

Remove a driver from the global driver list.

Parameters

<code><i>pciDriver_</i></code>	Pointer to the driver object to remove from the global table
--------------------------------	--

Definition at line [261](#) of file [driver.h](#).

The documentation for this class was generated from the following files:

- [/home/moslevin/mark3-source/embedded/kernel/public/driver.h](#)
- [/home/moslevin/mark3-source/embedded/kernel/driver.cpp](#)

19.7 EventFlag Class Reference

The [EventFlag](#) class is a blocking object, similar to a semaphore or mutex, commonly used for synchronizing thread execution based on events occurring within the system.

```
#include <eventflag.h>
```

Inheritance diagram for EventFlag:

Public Member Functions

- void [Init](#) ()
Init Initializes the [EventFlag](#) object prior to use.
- uint16_t [Wait](#) (uint16_t u16Mask_, [EventFlagOperation_t](#) eMode_)
Wait - Block a thread on the specific flags in this event flag group.
- uint16_t [Wait](#) (uint16_t u16Mask_, [EventFlagOperation_t](#) eMode_, uint32_t u32TimeMS_)
Wait - Block a thread on the specific flags in this event flag group.
- void [WakeMe](#) ([Thread](#) *pclOwner_)
WakeMe.
- void [Set](#) (uint16_t u16Mask_)
Set - Set additional flags in this object (logical OR).
- void [Clear](#) (uint16_t u16Mask_)
ClearFlags - Clear a specific set of flags within this object, specific by bitmask.
- uint16_t [GetMask](#) ()
GetMask Returns the state of the 16-bit bitmask within this object.

Private Member Functions

- uint16_t [Wait_i](#) (uint16_t u16Mask_, [EventFlagOperation_t](#) eMode_, uint32_t u32TimeMS_)
Wait_i.

Private Attributes

- uint16_t [m_u16SetMask](#)
Event flags currently set in this object.

Additional Inherited Members

19.7.1 Detailed Description

The [EventFlag](#) class is a blocking object, similar to a semaphore or mutex, commonly used for synchronizing thread execution based on events occurring within the system.

Each [EventFlag](#) object contains a 16-bit bitmask, which is used to trigger events on associated threads. Threads wishing to block, waiting for a specific event to occur can wait on any pattern within this 16-bit bitmask to be set. Here, we provide the ability for a thread to block, waiting for ANY bits in a specified mask to be set, or for ALL bits within a specific mask to be set. Depending on how the object is configured, the bits that triggered the wakeup can be automatically cleared once a match has occurred.

Examples:

[lab7_events/main.cpp](#).

Definition at line 46 of file [eventflag.h](#).

19.7.2 Member Function Documentation

19.7.2.1 void EventFlag::Clear (uint16_t u16Mask_)

ClearFlags - Clear a specific set of flags within this object, specific by bitmask.

Parameters

<i>u16Mask_</i>	- Bitmask of flags to clear
-----------------	-----------------------------

Examples:

[lab7_events/main.cpp](#).

Definition at line 292 of file [eventflag.cpp](#).

19.7.2.2 uint16_t EventFlag::GetMask ()

GetMask Returns the state of the 16-bit bitmask within this object.

Returns

The state of the 16-bit bitmask

Definition at line 301 of file [eventflag.cpp](#).

19.7.2.3 void EventFlag::Set (uint16_t u16Mask_)

Set - Set additional flags in this object (logical OR).

This API can potentially result in threads blocked on [Wait\(\)](#) to be unblocked.

Parameters

<i>u16Mask_</i>	- Bitmask of flags to set.
-----------------	----------------------------

Examples:

[lab7_events/main.cpp](#).

Definition at line 186 of file [eventflag.cpp](#).

19.7.2.4 uint16_t EventFlag::Wait (uint16_t u16Mask_, EventFlagOperation_t eMode_)

Wait - Block a thread on the specific flags in this event flag group.

Parameters

<i>u16Mask_</i>	- 16-bit bitmask to block on
<i>eMode_</i>	- EVENT_FLAG_ANY: Thread will block on any of the bits in the mask <ul style="list-style-type: none"> • EVENT_FLAG_ALL: Thread will block on all of the bits in the mask

Returns

Bitmask condition that caused the thread to unblock, or 0 on error or timeout

Examples:

[lab7_events/main.cpp](#).

Definition at line 168 of file [eventflag.cpp](#).

19.7.2.5 `uint16_t EventFlag::Wait (uint16_t u16Mask_, EventFlagOperation_t eMode_, uint32_t u32TimeMS_)`

Wait - Block a thread on the specific flags in this event flag group.

Parameters

<i>u16Mask_</i>	- 16-bit bitmask to block on
<i>eMode_</i>	- EVENT_FLAG_ANY: Thread will block on any of the bits in the mask <ul style="list-style-type: none"> • EVENT_FLAG_ALL: Thread will block on all of the bits in the mask
<i>u32TimeMS_</i>	- Time to block (in ms)

Returns

Bitmask condition that caused the thread to unblock, or 0 on error or timeout

Definition at line 179 of file [eventflag.cpp](#).

19.7.2.6 `uint16_t EventFlag::Wait_i (uint16_t u16Mask_, EventFlagOperation_t eMode_, uint32_t u32TimeMS_)`
[private]

Wait_i.

Internal abstraction used to manage both timed and untimed wait operations

Parameters

<i>u16Mask_</i>	- 16-bit bitmask to block on
<i>eMode_</i>	- EVENT_FLAG_ANY: Thread will block on any of the bits in the mask <ul style="list-style-type: none"> • EVENT_FLAG_ALL: Thread will block on all of the bits in the mask
<i>u32TimeMS_</i>	- Time to block (in ms)

Returns

Bitmask condition that caused the thread to unblock, or 0 on error or timeout

! If the Yield operation causes a new thread to be chosen, there will ! Be a context switch at the above [CS_EXIT\(\)](#). The original calling ! thread will not return back until a matching SetFlags call is made ! or a timeout occurs.

Definition at line 84 of file [eventflag.cpp](#).

19.7.2.7 void EventFlag::WakeMe (Thread * pOwner_)

WakeMe.

Wake the given thread, currently blocking on this object

Parameters

<code>pOwner_</code>	Pointer to the owner thread to unblock.
----------------------	---

Definition at line 76 of file [eventflag.cpp](#).

The documentation for this class was generated from the following files:

- [/home/moslevin/mark3-source/embedded/kernel/public/eventflag.h](#)
- [/home/moslevin/mark3-source/embedded/kernel/eventflag.cpp](#)

19.8 FakeThread_t Struct Reference

If the kernel is set up to use an idle function instead of an idle thread, we use a placeholder data structure to "simulate" the effect of having an idle thread in the system.

```
#include <thread.h>
```

Public Attributes

- [K_WORD * m_pwStackTop](#)
Pointer to the top of the thread's stack.
- [K_WORD * m_pwStack](#)
Pointer to the thread's stack.
- [uint8_t m_u8ThreadID](#)
Thread ID.
- [PORT_PRIO_TYPE m_uXPriority](#)
Default priority of the thread.
- [PORT_PRIO_TYPE m_uXCurPriority](#)
Current priority of the thread (priority inheritance)
- [ThreadState_t m_eState](#)
Enum indicating the thread's current state.

19.8.1 Detailed Description

If the kernel is set up to use an idle function instead of an idle thread, we use a placeholder data structure to "simulate" the effect of having an idle thread in the system.

When cast to a [Thread](#), this data structure will still result in `GetPriority()` calls being valid, which is all that is needed to support the tick-based/tickless times – while saving a fairly decent chunk of RAM on a small micro.

Note that this struct must have the same memory layout as the [Thread](#) class up to the last item.

Definition at line 483 of file [thread.h](#).

The documentation for this struct was generated from the following file:

- [/home/moslevin/mark3-source/embedded/kernel/public/thread.h](#)

19.9 GlobalMessagePool Class Reference

Implements a list of message objects shared between all threads.

```
#include <message.h>
```

Static Public Member Functions

- static void [Init](#) ()
Init.
- static void [Push](#) ([Message](#) *pclMessage_)
Push.
- static [Message](#) * [Pop](#) ()
Pop.
- static [Message](#) * [GetHead](#) ()
GetHead.
- static [MessagePool](#) * [GetPool](#) ()
GetPool.

Static Private Attributes

- static [Message](#) [m_aclMessagePool](#) [[GLOBAL_MESSAGE_POOL_SIZE](#)]
Array of message objects that make up the message pool.

19.9.1 Detailed Description

Implements a list of message objects shared between all threads.

Definition at line 208 of file [message.h](#).

19.9.2 Member Function Documentation

19.9.2.1 [Message](#) * [GlobalMessagePool::GetHead](#) () [static]

[GetHead](#).

Return a pointer to the first element in the message list

Returns

Pointer to head message element, or NULL if empty

Definition at line 112 of file [message.cpp](#).

19.9.2.2 [MessagePool](#) * [GlobalMessagePool::GetPool](#) () [static]

[GetPool](#).

Get the pointer to the underlying message pool object

Returns

Pointer to message pool.

Definition at line 118 of file [message.cpp](#).

19.9.2.3 void GlobalMessagePool::Init (void) [static]

Init.

Initialize the message queue prior to use

Definition at line 89 of file [message.cpp](#).

19.9.2.4 Message * GlobalMessagePool::Pop () [static]

Pop.

Pop a message from the global queue, returning it to the user to be popu32ated before sending by a transmitter.

Returns

Pointer to a [Message](#) object

Examples:

[lab8_messages/main.cpp](#).

Definition at line 106 of file [message.cpp](#).

19.9.2.5 void GlobalMessagePool::Push (Message * pclMessage_) [static]

Push.

Return a previously-claimed message object back to the global queue. used once the message has been processed by a receiver.

Parameters

<i>pclMessage_</i>	Pointer to the Message object to return back to the global queue
--------------------	--

Examples:

[lab8_messages/main.cpp](#).

Definition at line 100 of file [message.cpp](#).

The documentation for this class was generated from the following files:

- [/home/moslevin/mark3-source/embedded/kernel/public/message.h](#)
- [/home/moslevin/mark3-source/embedded/kernel/message.cpp](#)

19.10 Kernel Class Reference

Class that encapsulates all of the kernel startup functions.

```
#include <kernel.h>
```

Static Public Member Functions

- static void [Init](#) (void)
Kernel Initialization Function, call before any other OS function.
- static void [Start](#) (void)

Start the operating system kernel - the current execution context is cancelled, all kernel services are started, and the processor resumes execution at the entrypoint for the highest-priority thread.

- static bool [IsStarted](#) ()
IsStarted.
- static void [SetPanic](#) ([PanicFunc_t](#) pfPanic_)
SetPanic Set a function to be called when a kernel panic occurs, giving the user to determine the behavior when a catastrophic failure is observed.
- static bool [IsPanic](#) ()
IsPanic Returns whether or not the kernel is in a panic state.
- static void [Panic](#) (uint16_t u16Cause_)
Panic Cause the kernel to enter its panic state.
- static void [SetIdleFunc](#) ([IdleFunc_t](#) pfIdle_)
SetIdleFunc Set the function to be called when no active threads are available to be scheduled by the scheduler.
- static void [IdleFunc](#) (void)
IdleFunc Call the low-priority idle function when no active threads are available to be scheduled.
- static [Thread](#) * [GetIdleThread](#) (void)
GetIdleThread Return a pointer to the [Kernel](#)'s idle thread object to the user.
- static void [SetThreadCreateCallout](#) ([ThreadCreateCallout_t](#) pfCreate_)
SetThreadCreateCallout.
- static void [SetThreadExitCallout](#) ([ThreadExitCallout_t](#) pfExit_)
SetThreadExitCallout.
- static void [SetThreadContextSwitchCallout](#) ([ThreadContextCallout_t](#) pfContext_)
SetThreadContextSwitchCallout.
- static [ThreadCreateCallout_t](#) [GetThreadCreateCallout](#) (void)
GetThreadCreateCallout.
- static [ThreadExitCallout_t](#) [GetThreadExitCallout](#) (void)
GetThreadExitCallout.
- static [ThreadContextCallout_t](#) [GetThreadContextSwitchCallout](#) (void)
GetThreadContextSwitchCallout.

Static Private Attributes

- static bool [m_bIsStarted](#)
true if kernel is running, false otherwise
- static bool [m_bIsPanic](#)
true if kernel is in panic state, false otherwise
- static [PanicFunc_t](#) [m_pfPanic](#)
set panic function
- static [IdleFunc_t](#) [m_pfIdle](#)
set idle function
- static [FakeThread_t](#) [m_clIdle](#)
Idle thread object (note: not a real thread)
- static [ThreadCreateCallout_t](#) [m_pfThreadCreateCallout](#)
Function to call on thread creation.
- static [ThreadExitCallout_t](#) [m_pfThreadExitCallout](#)
Function to call on thread exit.
- static [ThreadContextCallout_t](#) [m_pfThreadContextCallout](#)
Function to call on context switch.

19.10.1 Detailed Description

Class that encapsulates all of the kernel startup functions.

Definition at line 44 of file [kernel.h](#).

19.10.2 Member Function Documentation

19.10.2.1 `static Thread* Kernel::GetIdleThread(void) [inline],[static]`

GetIdleThread Return a pointer to the [Kernel](#)'s idle thread object to the user.

Note that the [Thread](#) object involved is to be used for comparisons only – the thread itself is "virtual", and doesn't represent a unique execution context with its own stack.

Returns

Pointer to the [Kernel](#)'s idle thread object

Definition at line 122 of file [kernel.h](#).

19.10.2.2 `static ThreadContextCallout_t Kernel::GetThreadContextSwitchCallout(void) [inline],[static]`

GetThreadContextSwitchCallout.

Return the current function called on every [Thread::ContextSwitchSWI\(\)](#)

Returns

Pointer to the currently-installed callout function, or NULL if not set.

Definition at line 190 of file [kernel.h](#).

19.10.2.3 `static ThreadCreateCallout_t Kernel::GetThreadCreateCallout(void) [inline],[static]`

GetThreadCreateCallout.

Return the current function called on every [Thread::Init\(\)](#);

Returns

Pointer to the currently-installed callout function, or NULL if not set.

Definition at line 172 of file [kernel.h](#).

19.10.2.4 `static ThreadExitCallout_t Kernel::GetThreadExitCallout(void) [inline],[static]`

GetThreadExitCallout.

Return the current function called on every [Thread::Exit\(\)](#);

Returns

Pointer to the currently-installed callout function, or NULL if not set.

Definition at line 181 of file [kernel.h](#).

19.10.2.5 void Kernel::Init (void) [static]

[Kernel](#) Initialization Function, call before any other OS function.

Initializes all global resources used by the operating system. This must be called before any other kernel function is invoked.

Examples:

[buffalogger/main.cpp](#), [lab10_notifications/main.cpp](#), [lab11_mailboxes/main.cpp](#), [lab1_kernel_setup/main.cpp](#), [lab2_idle_function/main.cpp](#), [lab3_round_robin/main.cpp](#), [lab4_semaphores/main.cpp](#), [lab5_mutexes/main.cpp](#), [lab6_timers/main.cpp](#), [lab7_events/main.cpp](#), [lab8_messages/main.cpp](#), and [lab9_dynamic_threads/main.cpp](#).

Definition at line 67 of file [kernel.cpp](#).

19.10.2.6 static bool Kernel::IsPanic () [inline],[static]

IsPanic Returns whether or not the kernel is in a panic state.

Returns

Whether or not the kernel is in a panic state

Definition at line 90 of file [kernel.h](#).

19.10.2.7 static bool Kernel::IsStarted () [inline],[static]

IsStarted.

Returns

Whether or not the kernel has started - true = running, false = not started

Definition at line 77 of file [kernel.h](#).

19.10.2.8 void Kernel::Panic (uint16_t u16Cause_) [static]

Panic Cause the kernel to enter its panic state.

Parameters

<i>u16Cause_</i>	Reason for the kernel panic
------------------	-----------------------------

Definition at line 110 of file [kernel.cpp](#).

19.10.2.9 static void Kernel::SetIdleFunc (IdleFunc_t pIdle_) [inline],[static]

SetIdleFunc Set the function to be called when no active threads are available to be scheduled by the scheduler.

Parameters

<i>pIdle_</i>	Pointer to the idle function
---------------	------------------------------

Examples:

[lab2_idle_function/main.cpp](#).

Definition at line 103 of file [kernel.h](#).

19.10.2.10 `static void Kernel::SetPanic (PanicFunc_t pfPanic_) [inline],[static]`

SetPanic Set a function to be called when a kernel panic occurs, giving the user to determine the behavior when a catastrophic failure is observed.

Parameters

<i>pfPanic_</i>	Panic function pointer
-----------------	------------------------

Definition at line 85 of file [kernel.h](#).

```
19.10.2.11 static void Kernel::SetThreadContextSwitchCallout ( ThreadContextCallout_t pfContext_ ) [inline],
           [static]
```

SetThreadContextSwitchCallout.

Set a function to be called on each context switch.

A callout is only executed if this method has been called to set a valid handler function.

Parameters

<i>pfContext_</i>	Pointer to a function to call on context switch
-------------------	---

Examples:

[lab9_dynamic_threads/main.cpp](#).

Definition at line 159 of file [kernel.h](#).

```
19.10.2.12 static void Kernel::SetThreadCreateCallout ( ThreadCreateCallout_t pfCreate_ ) [inline], [static]
```

SetThreadCreateCallout.

Set a function to be called on creation of a new thread. This callout is executed on the successful completion of a [Thread::Init\(\)](#) call. A callout is only executed if this method has been called to set a valid handler function.

Parameters

<i>pfCreate_</i>	Pointer to a function to call on thread creation
------------------	--

Examples:

[lab9_dynamic_threads/main.cpp](#).

Definition at line 136 of file [kernel.h](#).

```
19.10.2.13 static void Kernel::SetThreadExitCallout ( ThreadExitCallout_t pfExit_ ) [inline], [static]
```

SetThreadExitCallout.

Set a function to be called on thread exit. This callout is executed from the beginning of [Thread::Exit\(\)](#).

A callout is only executed if this method has been called to set a valid handler function.

Parameters

<i>pfCreate_</i>	Pointer to a function to call on thread exit
------------------	--

Examples:

[lab9_dynamic_threads/main.cpp](#).

Definition at line 148 of file [kernel.h](#).

19.10.2.14 void Kernel::Start (void) [static]

Start the operating system kernel - the current execution context is cancelled, all kernel services are started, and the processor resumes execution at the entrypoint for the highest-priority thread.

You must have at least one thread added to the kernel before calling this function, otherwise the behavior is undefined. The exception to this is if the system is configured to use the threadless idle hook, in which case the kernel is allowed to run without any ready threads.

Examples:

[buffalogger/main.cpp](#), [lab10_notifications/main.cpp](#), [lab11_mailboxes/main.cpp](#), [lab1_kernel_setup/main.cpp](#), [lab2_idle_function/main.cpp](#), [lab3_round_robin/main.cpp](#), [lab4_semaphores/main.cpp](#), [lab5_mutexes/main.cpp](#), [lab6_timers/main.cpp](#), [lab7_events/main.cpp](#), [lab8_messages/main.cpp](#), and [lab9_dynamic_threads/main.cpp](#).

Definition at line 101 of file [kernel.cpp](#).

The documentation for this class was generated from the following files:

- [/home/moslevin/mark3-source/embedded/kernel/kernel.cpp](#)

19.11 KernelAware Class Reference

The [KernelAware](#) class.

```
#include <kernelaware.h>
```

Static Public Member Functions

- static void [ProfileInit](#) (const char *szStr_)
ProfileInit.
- static void [ProfileStart](#) (void)
ProfileStart.
- static void [ProfileStop](#) (void)
ProfileStop.
- static void [ProfileReport](#) (void)
ProfileReport.
- static void [ExitSimulator](#) (void)
ExitSimulator.
- static void [Print](#) (const char *szStr_)
Print.
- static void [Trace](#) (uint16_t u16File_, uint16_t u16Line_)
Trace.
- static void [Trace](#) (uint16_t u16File_, uint16_t u16Line_, uint16_t u16Arg1_)
Trace.
- static void [Trace](#) (uint16_t u16File_, uint16_t u16Line_, uint16_t u16Arg1_, uint16_t u16Arg2_)
Trace.
- static bool [IsSimulatorAware](#) (void)
IsSimulatorAware.

Static Private Member Functions

- static void [Trace_i](#) (uint16_t u16File_, uint16_t u16Line_, uint16_t u16Arg1_, uint16_t u16Arg2_, [KernelAwareCommand_t](#) eCmd_)
Trace_i.

19.11.1 Detailed Description

The [KernelAware](#) class.

This class contains functions that are used to trigger kernel-aware functionality within a supported simulation environment (i.e. fIAVR).

These static methods operate on a singleton set of global variables, which are monitored for changes from within the simulator. The simulator hooks into these variables by looking for the correctly-named symbols in an elf-formatted binary being run and registering callbacks that are called whenever the variables are changed. On each change of the command variable, the kernel-aware data is analyzed and interpreted appropriately.

If these methods are run in an unsupported simulator or on actual hardware the commands generally have no effect (except for the exit-on-reset command, which will result in a jump-to-0 reset).

Definition at line 64 of file [kernelaware.h](#).

19.11.2 Member Function Documentation

19.11.2.1 void KernelAware::ExitSimulator (void) [static]

ExitSimulator.

Instruct the kernel-aware simulator to terminate (destroying the virtual CPU).

Definition at line 109 of file [kernelaware.cpp](#).

19.11.2.2 bool KernelAware::IsSimulatorAware (void) [static]

IsSimulatorAware.

use this function to determine whether or not the code is running on a simulator that is aware of the kernel.

Returns

true - the application is being run in a kernel-aware simulator. false - otherwise.

Definition at line 154 of file [kernelaware.cpp](#).

19.11.2.3 void KernelAware::Print (const char * szStr_) [static]

Print.

Instruct the kernel-aware simulator to print a char string

Parameters

<i>szStr_</i>	
---------------	--

Examples:

[lab10_notifications/main.cpp](#), [lab11_mailboxes/main.cpp](#), [lab1_kernel_setup/main.cpp](#), [lab2_idle_function/main.cpp](#), [lab3_round_robin/main.cpp](#), [lab4_semaphores/main.cpp](#), [lab5_mutexes/main.cpp](#), [lab6_timers/main.cpp](#), [lab7_events/main.cpp](#), [lab8_messages/main.cpp](#), and [lab9_dynamic_threads/main.cpp](#).

Definition at line 145 of file [kernelaware.cpp](#).

19.11.2.4 void KernelAware::ProfileInit (const char * szStr_) [static]

ProfileInit.

Initializes the kernel-aware profiler. This function instructs the kernel-aware simulator to reset its accounting variables, and prepare to start counting profiling data tagged to the given string. How this is handled is the responsibility of the simulator.

Parameters

<i>szStr_</i>	String to use as a tag for the profiling session.
---------------	---

Definition at line 82 of file [kernelaware.cpp](#).

19.11.2.5 void KernelAware::ProfileReport (void) [static]

ProfileReport.

Instruct the kernel-aware simulator to print a report for its current profiling data.

Definition at line 103 of file [kernelaware.cpp](#).

19.11.2.6 void KernelAware::ProfileStart (void) [static]

ProfileStart.

Instruct the kernel-aware simulator to begin counting cycles towards the current profiling counter.

Definition at line 91 of file [kernelaware.cpp](#).

19.11.2.7 void KernelAware::ProfileStop (void) [static]

ProfileStop.

Instruct the kernel-aware simulator to end counting cycles relative to the current profiling counter's iteration.

Definition at line 97 of file [kernelaware.cpp](#).

19.11.2.8 void KernelAware::Trace (uint16_t u16File_, uint16_t u16Line_) [static]

Trace.

Insert a kernel trace statement into the kernel-aware simulator's debug data stream.

Parameters

<i>u16File_</i>	16-bit code representing the file
<i>u16Line_</i>	16-bit code representing the line in the file

Examples:

[lab11_mailboxes/main.cpp](#), [lab8_messages/main.cpp](#), and [lab9_dynamic_threads/main.cpp](#).

Definition at line 115 of file [kernelaware.cpp](#).

19.11.2.9 void KernelAware::Trace (uint16_t u16File_, uint16_t u16Line_, uint16_t u16Arg1_) [static]

Trace.

Insert a kernel trace statement into the kernel-aware simulator's debug data stream.

Parameters

<i>u16File_</i>	16-bit code representing the file
<i>u16Line_</i>	16-bit code representing the line in the file
<i>u16Arg1_</i>	16-bit argument to the format string.

Definition at line 121 of file [kernelaware.cpp](#).

```
19.11.2.10 void KernelAware::Trace ( uint16_t u16File_, uint16_t u16Line_, uint16_t u16Arg1_, uint16_t u16Arg2_ )
           [static]
```

Trace.

Insert a kernel trace statement into the kernel-aware simulator's debug data stream.

Parameters

<i>u16File_</i>	16-bit code representing the file
<i>u16Line_</i>	16-bit code representing the line in the file
<i>u16Arg1_</i>	16-bit argument to the format string.
<i>u16Arg2_</i>	16-bit argument to the format string.

Definition at line 126 of file [kernelaware.cpp](#).

```
19.11.2.11 void KernelAware::Trace_i ( uint16_t u16File_, uint16_t u16Line_, uint16_t u16Arg1_, uint16_t u16Arg2_,
           KernelAwareCommand_t eCmd_ ) [static],[private]
```

Trace_i.

Private function by which the class's [Trace\(\)](#) methods are reflected, which allows u16 to realize a modest code saving.

Parameters

<i>u16File_</i>	16-bit code representing the file
<i>u16Line_</i>	16-bit code representing the line in the file
<i>u16Arg1_</i>	16-bit argument to the format string.
<i>u16Arg2_</i>	16-bit argument to the format string.
<i>eCmd_</i>	Code indicating the number of arguments to emit.

Definition at line 132 of file [kernelaware.cpp](#).

The documentation for this class was generated from the following files:

- [/home/moslevin/mark3-source/embedded/kernel/kernelaware.cpp](#)

19.12 KernelAwareData_t Union Reference

This structure is used to communicate between the kernel and a kernel- aware host.

Public Attributes

- volatile uint16_t [au16Buffer](#) [5]
Raw binary contents of the struct.

- The [Profiler](#) struct contains data related to the code-execution profiling functionality provided by a kernel-aware host simulator.

The Trace struct contains data related to the display and output of kernel-trace strings on a kernel-aware host.

The Print struct contains data related to the display of arbitrary null-terminated ASCII strings on the kernel-aware host.

19.12.1 Detailed Description

This structure is used to communicate between the kernel and a kernel-aware host.

Its data contents is interpreted differently depending on the command executed (by means of setting the `g_u8KACommand` variable, as is done in the command handlers in this module). As a result, any changes to this struct by way of modifying or adding data must be mirrored in the kernel-aware simulator.

Definition at line 48 of file [kernelaware.cpp](#).

The documentation for this union was generated from the following file:

- [/home/moslevin/mark3-source/embedded/kernel/kernelaware.cpp](#)

19.13 KernelSWI Class Reference

Class providing the software-interrupt required for context-switching in the kernel.

```
#include <kernelswi.h>
```

Static Public Member Functions

- static void [Config](#) (void)
Config.
- static void [Start](#) (void)
Start.
- static void [Stop](#) (void)
Stop.
- static void [Clear](#) (void)
Clear.
- static void [Trigger](#) (void)
Trigger.
- static uint8_t [DI](#) ()
DI.
- static void [RI](#) (bool bEnable_)
RI.

19.13.1 Detailed Description

Class providing the software-interrupt required for context-switching in the kernel.

Definition at line 31 of file [kernelswi.h](#).

19.13.2 Member Function Documentation

19.13.2.1 void KernelSWI::Clear (void) [static]

Clear.

Clear the software interrupt

Definition at line 68 of file [kernelswi.cpp](#).

19.13.2.2 void KernelSWI::Config (void) [static]

Config.

Configure the software interrupt - must be called before any other software interrupt functions are called.

Definition at line 29 of file [kernelswi.cpp](#).

19.13.2.3 uint8_t KernelSWI::DI () [static]

DI.

Disable the SWI flag itself

Returns

previous status of the SWI, prior to the DI call

Definition at line 50 of file [kernelswi.cpp](#).

19.13.2.4 void KernelSWI::RI (bool bEnable_) [static]

RI.

Restore the state of the SWI to the value specified

Parameters

<i>bEnable_</i>	true - enable the SWI, false - disable SWI
-----------------	--

Definition at line 58 of file [kernelswi.cpp](#).

19.13.2.5 void KernelSWI::Start (void) [static]

Start.

Enable ("Start") the software interrupt functionality

Definition at line 37 of file [kernelswi.cpp](#).

19.13.2.6 void KernelSWI::Stop (void) [static]

Stop.

Disable the software interrupt functionality

Definition at line 44 of file [kernelswi.cpp](#).

19.13.2.7 void KernelSWI::Trigger (void) [static]

Trigger.

Call the software interrupt

Definition at line 74 of file [kernelswi.cpp](#).

The documentation for this class was generated from the following files:

GetOvertime.
- static void [ClearExpiry](#) (void)
ClearExpiry.
- static [PORT_TIMER_COUNT_TYPE](#) [Read](#) (void)
Read.

19.14.1 Detailed Description

Hardware timer interface, used by all scheduling/timer subsystems.

Definition at line 31 of file [kerneltimer.h](#).

19.14.2 Member Function Documentation

19.14.2.1 void KernelTimer::ClearExpiry (void) [static]

ClearExpiry.

Clear the hardware timer expiry register

Definition at line 136 of file [kerneltimer.cpp](#).

19.14.2.2 void KernelTimer::Config (void) [static]

Config.

Initializes the kernel timer before use

Definition at line 33 of file [kerneltimer.cpp](#).

19.14.2.3 uint8_t KernelTimer::DI (void) [static]

DI.

Disable the kernel timer's expiry interrupt

Definition at line 144 of file [kerneltimer.cpp](#).

19.14.2.4 void KernelTimer::EI (void) [static]

EI.

Enable the kernel timer's expiry interrupt

Definition at line 157 of file [kerneltimer.cpp](#).

19.14.2.5 PORT_TIMER_COUNT_TYPE KernelTimer::GetOvertime (void) [static]

GetOvertime.

Return the number of ticks that have elapsed since the last expiry.

Returns

Number of ticks that have elapsed after last timer expiration

Definition at line 112 of file [kerneltimer.cpp](#).

19.14.2.6 PORT_TIMER_COUNT_TYPE KernelTimer::Read (void) [static]

Read.

Safely read the current value in the timer register

Returns

Value held in the timer register

Examples:

[lab9_dynamic_threads/main.cpp](#).

Definition at line 66 of file [kerneltimer.cpp](#).

19.14.2.7 `void KernelTimer::RI (bool bEnable_) [static]`

RI.

Retstore the state of the kernel timer's expiry interrupt.

Parameters

<i>bEnable_</i>	1 enable, 0 disable
-----------------	---------------------

Definition at line 163 of file [kerneltimer.cpp](#).

19.14.2.8 `PORT_TIMER_COUNT_TYPE KernelTimer::SetExpiry (uint32_t u32Interval_) [static]`

SetExpiry.

Resets the kernel timer's expiry interval to the specified value

Parameters

<i>u32Interval_</i>	Desired interval in ticks to set the timer for
---------------------	--

Returns

Actual number of ticks set (may be less than desired)

Definition at line 118 of file [kerneltimer.cpp](#).

19.14.2.9 `void KernelTimer::Start (void) [static]`

Start.

Starts the kernel time (must be configured first)

Definition at line 39 of file [kerneltimer.cpp](#).

19.14.2.10 `void KernelTimer::Stop (void) [static]`

Stop.

Shut down the kernel timer, used when no timers are scheduled

Definition at line 54 of file [kerneltimer.cpp](#).

19.14.2.11 `PORT_TIMER_COUNT_TYPE KernelTimer::SubtractExpiry (PORT_TIMER_COUNT_TYPE uInterval_) [static]`

SubtractExpiry.

Subtract the specified number of ticks from the timer's expiry count register. Returns the new expiry value stored in the register.

Parameters

<i>u32Interval_</i>	Time (in HW-specific) ticks to subtract
---------------------	---

Returns

Value in ticks stored in the timer's expiry register

Definition at line 84 of file [kerneltimer.cpp](#).

19.14.2.12 **PORT_TIMER_COUNT_TYPE** KernelTimer::TimeToExpiry (void) [static]

TimeToExpiry.

Returns the number of ticks remaining before the next timer expiry.

Returns

Time before next expiry in platform-specific ticks

Definition at line 95 of file [kerneltimer.cpp](#).

The documentation for this class was generated from the following files:

- /home/moslevin/mark3-source/embedded/kernel/cpu/avr/atmega328p/gcc/public/[kerneltimer.h](#)
- /home/moslevin/mark3-source/embedded/kernel/cpu/avr/atmega328p/gcc/[kerneltimer.cpp](#)

19.15 LinkList Class Reference

Abstract-data-type from which all other linked-lists are derived.

```
#include <ll.h>
```

Inheritance diagram for LinkList:

Public Member Functions

- void [Init](#) ()
Init.
- [LinkListNode](#) * [GetHead](#) ()
GetHead.
- [LinkListNode](#) * [GetTail](#) ()
GetTail.

Protected Attributes

- [LinkListNode](#) * [m_pstHead](#)
Pointer to the head node in the list.
- [LinkListNode](#) * [m_pstTail](#)
Pointer to the tail node in the list.

19.15.1 Detailed Description

Abstract-data-type from which all other linked-lists are derived.

Definition at line 109 of file [ll.h](#).

19.15.2 Member Function Documentation

19.15.2.1 LinkListNode* LinkList::GetHead () [inline]

GetHead.

Get the head node in the linked list

Returns

Pointer to the head node in the list

Definition at line 134 of file [ll.h](#).

19.15.2.2 LinkListNode* LinkList::GetTail () [inline]

GetTail.

Get the tail node of the linked list

Returns

Pointer to the tail node in the list

Definition at line 142 of file [ll.h](#).

19.15.2.3 void LinkList::Init (void) [inline]

Init.

Clear the linked list.

Definition at line 121 of file [ll.h](#).

The documentation for this class was generated from the following file:

ClearNode.

Protected Attributes

- [LinkedListNode](#) * [next](#)

Pointer to the next node in the list.

- [LinkedListNode](#) * [prev](#)

Pointer to the previous node in the list.

Friends

- class **LinkedList**
- class **DoubleLinkedList**
- class **CircularLinkedList**
- class **ThreadList**

19.16.1 Detailed Description

Basic linked-list node data structure.

This data is managed by the linked-list class types, and can be used transparently between them.

Definition at line 68 of file [ll.h](#).

19.16.2 Member Function Documentation

19.16.2.1 void [LinkedListNode::ClearNode](#) () [protected]

ClearNode.

Initialize the linked list node, clearing its next and previous node.

Definition at line 40 of file [ll.cpp](#).

19.16.2.2 [LinkedListNode](#)* [LinkedListNode::GetNext](#) (void) [inline]

GetNext.

Returns a pointer to the next node in the list.

Returns

a pointer to the next node in the list.

Definition at line 90 of file [ll.h](#).

19.16.2.3 LinkListNode* LinkListNode::GetPrev (void) [inline]

GetPrev.

Returns a pointer to the previous node in the list.

Returns

a pointer to the previous node in the list.

Definition at line 98 of file [ll.h](#).

MoveTailBackward.
- void [MoveHeadBackward](#) (void)
MoveHeadBackward.
- bool [Send_i](#) (const void *pvData_, bool bTail_, uint32_t u32WaitTimeMS_)
Send_i.
- bool [Receive_i](#) (const void *pvData_, bool bTail_, uint32_t u32WaitTimeMS_)
Receive_i.

Private Attributes

- uint16_t [m_u16Head](#)
Current head index.
- uint16_t [m_u16Tail](#)
Current tail index.
- uint16_t [m_u16Count](#)
Count of items in the mailbox.
- volatile uint16_t [m_u16Free](#)
Current number of free slots in the mailbox.
- uint16_t [m_u16ElementSize](#)
Size of the objects tracked in this mailbox.
- const void * [m_pvBuffer](#)
Pointer to the data-buffer managed by this mailbox.
- [Semaphore m_clRecvSem](#)
Counting semaphore used to synchronize threads on the object.
- [Semaphore m_clSendSem](#)
Binary semaphore for send-blocked threads.

19.17.1 Detailed Description

The [Mailbox](#) class implements an IPC mechnism based on envelopes containing data of a fixed size (configured at initialization) that reside within a buffer of memory provided by the user.

Examples:

[lab11_mailboxes/main.cpp](#).

Definition at line 35 of file [mailbox.h](#).

19.17.2 Member Function Documentation

19.17.2.1 void [Mailbox::CopyData](#) (const void * *src_*, const void * *dst_*, uint16_t *len_*) [inline], [private]

[CopyData](#).

Perform a direct byte-copy from a source to a destination object.

Parameters

<i>src_</i>	Pointer to an object to read from
<i>dst_</i>	Pointer to an object to write to
<i>len_</i>	Length to copy (in bytes)

Definition at line 238 of file [mailbox.h](#).

19.17.2.2 `void* Mailbox::GetHeadPointer (void) [inline],[private]`

GetHeadPointer.

Return a pointer to the current head of the mailbox's internal circular buffer.

Returns

pointer to the head element in the mailbox

Definition at line 207 of file [mailbox.h](#).

19.17.2.3 `void* Mailbox::GetTailPointer (void) [inline],[private]`

GetTailPointer.

Return a pointer to the current tail of the mailbox's internal circular buffer.

Returns

pointer to the tail element in the mailbox

Definition at line 222 of file [mailbox.h](#).

19.17.2.4 `void Mailbox::Init (void * pvBuffer_, uint16_t u16BufferSize_, uint16_t u16ElementSize_)`

Init.

Initialize the mailbox object prior to its use. This must be called before any calls can be made to the object.

Parameters

<i>pvBuffer_</i>	Pointer to the static buffer to use for the mailbox
<i>u16BufferSize_</i>	Size of the mailbox buffer, in bytes
<i>u16ElementSize_</i>	Size of each envelope, in bytes

Examples:

[lab11_mailboxes/main.cpp](#).

Definition at line 51 of file [mailbox.cpp](#).

19.17.2.5 `void Mailbox::MoveHeadBackward (void) [inline],[private]`

MoveHeadBackward.

Move the head index backward one element

Definition at line 291 of file [mailbox.h](#).

19.17.2.6 `void Mailbox::MoveHeadForward (void) [inline],[private]`

MoveHeadForward.

Move the head index forward one element

Definition at line 265 of file [mailbox.h](#).

19.17.2.7 `void Mailbox::MoveTailBackward (void) [inline],[private]`

MoveTailBackward.

Move the tail index backward one element

Definition at line 278 of file [mailbox.h](#).

19.17.2.8 `void Mailbox::MoveTailForward (void) [inline],[private]`

MoveTailForward.

Move the tail index forward one element

Definition at line 252 of file [mailbox.h](#).

19.17.2.9 `void Mailbox::Receive (void * pvData_)`

Receive.

Read one envelope from the head of the mailbox. If the mailbox is currently empty, the calling thread will block until an envelope is delivered.

Parameters

<i>pvData_</i>	Pointer to a buffer that will have the envelope's contents copied into upon delivery.
----------------	---

Examples:

[lab11_mailboxes/main.cpp](#).

Definition at line 89 of file [mailbox.cpp](#).

19.17.2.10 `bool Mailbox::Receive (void * pvData_, uint32_t u32TimeoutMS_)`

Receive.

Read one envelope from the head of the mailbox. If the mailbox is currently empty, the calling thread will block until an envelope is delivered, or the specified time has elapsed without delivery.

Parameters

<i>pvData_</i>	Pointer to a buffer that will have the envelope's contents copied into upon delivery.
<i>u32TimeoutMS_</i>	Maximum time to wait for delivery.

Returns

true - envelope was delivered, false - delivery timed out.

Definition at line 102 of file [mailbox.cpp](#).

19.17.2.11 `bool Mailbox::Receive_i (const void * pvData_, bool bTail_, uint32_t u32WaitTimeMS_) [private]`

Receive_i.

Internal method which implements all Read() methods in the class.

Parameters

<i>pvData_</i>	Pointer to the envelope data
<i>bTail_</i>	true - read from tail, false - read from head
<i>u32WaitTimeMS_</i>	Time to wait before timeout (in ms).

Returns

true - read successfully, false - timeout.

Definition at line 244 of file [mailbox.cpp](#).

19.17.2.12 `void Mailbox::ReceiveTail (void * pvData_)`

ReceiveTail.

Read one envelope from the tail of the mailbox. If the mailbox is currently empty, the calling thread will block until an envelope is delivered.

Parameters

<i>pvData_</i>	Pointer to a buffer that will have the envelope's contents copied into upon delivery.
----------------	---

Definition at line 110 of file [mailbox.cpp](#).

19.17.2.13 `bool Mailbox::ReceiveTail (void * pvData_, uint32_t u32TimeoutMS_)`

ReceiveTail.

Read one envelope from the tail of the mailbox. If the mailbox is currently empty, the calling thread will block until an envelope is delivered, or the specified time has elapsed without delivery.

Parameters

<i>pvData_</i>	Pointer to a buffer that will have the envelope's contents copied into upon delivery.
<i>u32TimeoutMS_</i>	Maximum time to wait for delivery.

Returns

true - envelope was delivered, false - delivery timed out.

Definition at line 123 of file [mailbox.cpp](#).

19.17.2.14 `bool Mailbox::Send (void * pvData_)`

Send.

Send an envelope to the mailbox. This safely copies the data contents of the datastructure to the previously-initialized mailbox buffer. If there is a thread already blocking, awaiting delivery to the mailbox, it will be unblocked at this time.

This method delivers the envelope at the head of the mailbox.

Parameters

<i>pvData_</i>	Pointer to the data object to send to the mailbox.
----------------	--

Returns

true - envelope was delivered, false - mailbox is full.

Examples:

[lab11_mailboxes/main.cpp](#).

Definition at line 131 of file [mailbox.cpp](#).

19.17.2.15 `bool Mailbox::Send (void * pvData_, uint32_t u32TimeoutMS_)`

Send.

Send an envelope to the mailbox. This safely copies the data contents of the datastructure to the previously-initialized mailbox buffer. If there is a thread already blocking, awaiting delivery to the mailbox, it will be unblocked at this time.

This method delivers the envelope at the head of the mailbox.

Parameters

<i>pvData_</i>	Pointer to the data object to send to the mailbox.
<i>u32TimeoutMS_</i>	Maximum time to wait for a free transmit slot

Returns

true - envelope was delivered, false - mailbox is full.

Definition at line 156 of file [mailbox.cpp](#).

19.17.2.16 `bool Mailbox::Send_i (const void * pvData_, bool bTail_, uint32_t u32WaitTimeMS_)` [private]

Send_i.

Internal method which implements all [Send\(\)](#) methods in the class.

Parameters

<i>pvData_</i>	Pointer to the envelope data
<i>bTail_</i>	true - write to tail, false - write to head
<i>u32WaitTimeMS_</i>	Time to wait before timeout (in ms).

Returns

true - data successfully written, false - buffer full

Definition at line 174 of file [mailbox.cpp](#).

19.17.2.17 `bool Mailbox::SendTail (void * pvData_)`

SendTail.

Send an envelope to the mailbox. This safely copies the data contents of the datastructure to the previously-initialized mailbox buffer. If there is a thread already blocking, awaiting delivery to the mailbox, it will be unblocked at this time.

This method delivers the envelope at the tail of the mailbox.

Parameters

<i>pvData_</i>	Pointer to the data object to send to the mailbox.
----------------	--

Returns

true - envelope was delivered, false - mailbox is full.

Definition at line 143 of file [mailbox.cpp](#).

19.17.2.18 **bool** Mailbox::SendTail (void * *pvData_*, uint32_t *u32TimeoutMS_*)

SendTail.

Send an envelope to the mailbox. This safely copies the data contents of the datastructure to the previously-initialized mailbox buffer. If there is a thread already blocking, awaiting delivery to the mailbox, it will be unblocked at this time.

This method delivers the envelope at the tail of the mailbox.

Parameters

<i>pvData_</i>	Pointer to the data object to send to the mailbox.
<i>u32TimeoutMS_</i>	Maximum time to wait for a free transmit slot

Returns

true - envelope was delivered, false - mailbox is full.

Definition at line 164 of file [mailbox.cpp](#).

19.17.3 Member Data Documentation

19.17.3.1 **Semaphore** Mailbox::m_clSendSem [private]

Binary semaphore for send-blocked threads.

Definition at line 360 of file [mailbox.h](#).

The documentation for this class was generated from the following files:

- [/home/moslevin/mark3-source/embedded/kernel/public/mailbox.h](#)
- [/home/moslevin/mark3-source/embedded/kernel/mailbox.cpp](#)

19.18 Message Class Reference

Class to provide message-based IPC services in the kernel.

```
#include <message.h>
```

Inheritance diagram for Message:

Public Member Functions

- void [Init](#) ()
Init.
- void [SetData](#) (void *pvData_)
SetData.
- void * [GetData](#) ()
GetData.
- void [SetCode](#) (uint16_t u16Code_)
SetCode.
- uint16_t [GetCode](#) ()
GetCode.

Private Attributes

- void * [m_pvData](#)
Pointer to the message data.
- uint16_t [m_u16Code](#)
Message code, providing context for the message.

Additional Inherited Members

19.18.1 Detailed Description

Class to provide message-based IPC services in the kernel.

Examples:

[lab8_messages/main.cpp](#).

Definition at line 99 of file [message.h](#).

19.18.2 Member Function Documentation

19.18.2.1 uint16_t Message::GetCode () [inline]

GetCode.

Return the code set in the message upon receipt

Returns

user code set in the object

Examples:

[lab8_messages/main.cpp](#).

Definition at line 146 of file [message.h](#).

19.18.2.2 `void* Message::GetData () [inline]`

GetData.

Get the data pointer stored in the message upon receipt

Returns

Pointer to the data set in the message object

Examples:

[lab8_messages/main.cpp](#).

Definition at line 130 of file [message.h](#).

19.18.2.3 `void Message::Init (void) [inline]`

Init.

Initialize the data and code in the message.

Definition at line 108 of file [message.h](#).

19.18.2.4 `void Message::SetCode (uint16_t u16Code_) [inline]`

SetCode.

Set the code in the message before transmission

Parameters

<i>u16Code_</i>	Data code to set in the object
-----------------	--------------------------------

Examples:

[lab8_messages/main.cpp](#).

Definition at line 138 of file [message.h](#).

19.18.2.5 `void Message::SetData (void * pvData_) [inline]`

SetData.

Set the data pointer for the message before transmission.

Parameters

<i>pvData_</i>	Pointer to the data object to send in the message
----------------	---

Examples:

[lab8_messages/main.cpp](#).

Definition at line 122 of file [message.h](#).

The documentation for this class was generated from the following file:

- [/home/moslevin/mark3-source/embedded/kernel/public/message.h](#)

19.19 MessagePool Class Reference

Implements a list of message objects.

```
#include <message.h>
```

Public Member Functions

- void [Init](#) ()
Init.
- void [Push](#) ([Message](#) *pclMessage_)
Push.
- [Message](#) * [Pop](#) ()
Pop.
- [Message](#) * [GetHead](#) ()
GetHead.

Private Attributes

- [DoubleLinkedList](#) [m_clList](#)
Linked list used to manage the [Message](#) objects.

19.19.1 Detailed Description

Implements a list of message objects.

Definition at line 159 of file [message.h](#).

19.19.2 Member Function Documentation

19.19.2.1 [Message](#) * [MessagePool::GetHead](#) ()

[GetHead](#).

Return a pointer to the first element in the message list

Returns

Definition at line 83 of file [message.cpp](#).

19.19.2.2 void [MessagePool::Init](#) (void)

[Init](#).

Initialize the message queue prior to use

Definition at line 50 of file [message.cpp](#).

19.19.2.3 [Message](#) * [MessagePool::Pop](#) ()

[Pop](#).

Pop a message from the queue, returning it to the user to be populated before sending by a transmitter.

Returns

Pointer to a [Message](#) object

Definition at line 68 of file [message.cpp](#).

19.19.2.4 void MessagePool::Push (Message * pclMessage_)

Push.

Return a previously-claimed message object back to the queue. used once the message has been processed by a receiver.

Parameters

pclMessage_	Pointer to the Message object to return back to the queue
-----------------------------	---

Definition at line 56 of file [message.cpp](#).

The documentation for this class was generated from the following files:

- [/home/moslevin/mark3-source/embedded/kernel/public/message.h](#)
- [/home/moslevin/mark3-source/embedded/kernel/message.cpp](#)

19.20 MessageQueue Class Reference

List of messages, used as the channel for sending and receiving messages between threads.

```
#include <message.h>
```

Public Member Functions

- void [Init](#) ()
Init.
- [Message](#) * [Receive](#) ()
Receive.
- [Message](#) * [Receive](#) (uint32_t u32TimeWaitMS_)
Receive.
- void [Send](#) ([Message](#) *pclSrc_)
Send.
- uint16_t [GetCount](#) ()
GetCount.

Private Member Functions

- [Message](#) * [Receive_i](#) (uint32_t u32TimeWaitMS_)
Receive_i.

Private Attributes

- [Semaphore](#) [m_clSemaphore](#)
Counting semaphore used to manage thread blocking.
- [DoubleLinkedList](#) [m_clLinkList](#)
List object used to store messages.

19.20.1 Detailed Description

List of messages, used as the channel for sending and receiving messages between threads.

Examples:

[lab8_messages/main.cpp](#).

Definition at line 269 of file [message.h](#).

19.20.2 Member Function Documentation

19.20.2.1 uint16_t MessageQueue::GetCount ()

GetCount.

Return the number of messages pending in the "receive" queue.

Returns

Count of pending messages in the queue.

Definition at line 193 of file [message.cpp](#).

19.20.2.2 void MessageQueue::Init (void)

Init.

Initialize the message queue prior to use.

Examples:

[lab8_messages/main.cpp](#).

Definition at line 124 of file [message.cpp](#).

19.20.2.3 Message * MessageQueue::Receive ()

Receive.

Receive a message from the message queue. If the message queue is empty, the thread will block until a message is available.

Returns

Pointer to a message object at the head of the queue

Examples:

[lab8_messages/main.cpp](#).

Definition at line 130 of file [message.cpp](#).

19.20.2.4 Message * MessageQueue::Receive (uint32_t u32TimeWaitMS_)

Receive.

Receive a message from the message queue. If the message queue is empty, the thread will block until a message is available for the duration specified. If no message arrives within that duration, the call will return with NULL.

Parameters

<i>u32TimeWaitMS_</i>	The amount of time in ms to wait for a message before timing out and unblocking the waiting thread.
-----------------------	---

Returns

Pointer to a message object at the head of the queue or NULL on timeout.

Definition at line 141 of file [message.cpp](#).

19.20.2.5 **Message * MessageQueue::Receive_i (uint32_t u32TimeWaitMS_)** [private]

Receive_i.

Internal function used to abstract timed and un-timed Receive calls.

Parameters

<i>u32TimeWaitMS_</i>	Time (in ms) to block, 0 for un-timed call.
-----------------------	---

Returns

Pointer to a message, or 0 on timeout.

Definition at line 149 of file [message.cpp](#).

19.20.2.6 **void MessageQueue::Send (Message * pclSrc_)**

Send.

Send a message object into this message queue. Will un-block the first waiting thread blocked on this queue if that occurs.

Parameters

<i>pclSrc_</i>	Pointer to the message object to add to the queue
----------------	---

Examples:

[lab8_messages/main.cpp](#).

Definition at line 177 of file [message.cpp](#).

The documentation for this class was generated from the following files:

- [/home/moslevin/mark3-source/embedded/kernel/public/message.h](#)
- [/home/moslevin/mark3-source/embedded/kernel/message.cpp](#)

19.21 Mutex Class Reference

Mutual-exclusion locks, based on [BlockingObject](#).

```
#include <mutex.h>
```

Inheritance diagram for Mutex:

Public Member Functions

- void [Init](#) ()
Init.
- void [Claim](#) ()
Claim.
- bool [Claim](#) (uint32_t u32WaitTimeMS_)
Claim.
- void [WakeMe](#) ([Thread](#) *pclOwner_)
WakeMe.
- void [Release](#) ()
Release.

Private Member Functions

- uint8_t [WakeNext](#) ()
WakeNext.
- bool [Claim_i](#) (uint32_t u32WaitTimeMS_)
Claim_i.

Private Attributes

- uint8_t [m_u8Recurse](#)
The recursive lock-count when a mutex is claimed multiple times by the same owner.
- bool [m_bReady](#)
State of the mutex - true = ready, false = claimed.
- uint8_t [m_u8MaxPri](#)
Maximum priority of thread in queue, used for priority inheritance.
- [Thread](#) * [m_pclOwner](#)
Pointer to the thread that owns the mutex (when claimed)

Additional Inherited Members

19.21.1 Detailed Description

Mutual-exclusion locks, based on [BlockingObject](#).

Examples:

[lab5_mutexes/main.cpp](#).

Definition at line 68 of file [mutex.h](#).

19.21.2 Member Function Documentation

19.21.2.1 void Mutex::Claim (void)

Claim.

Claim the mutex. When the mutex is claimed, no other thread can claim a region protected by the object. If another [Thread](#) currently holds the [Mutex](#) when the Claim method is called, that [Thread](#) will block until the current owner of the mutex releases the [Mutex](#).

If the calling [Thread](#)'s priority is lower than that of a [Thread](#) that currently owns the [Mutex](#) object, then the priority of that [Thread](#) will be elevated to that of the highest-priority calling object until the [Mutex](#) is released. This property is known as "Priority Inheritance"

Note: A single thread can recursively claim a mutex up to a count of

1. Attempting to claim a mutex beyond that will cause a kernel panic.

Examples:

[lab5_mutexes/main.cpp](#).

Definition at line 215 of file [mutex.cpp](#).

19.21.2.2 bool Mutex::Claim (uint32_t u32WaitTimeMS_)

Claim.

Claim a mutex, with timeout.

Parameters

<i>u32WaitTimeMS_</i> S_	
-----------------------------	--

Returns

true - mutex was claimed within the time period specified
false - mutex operation timed-out before the claim operation.

Definition at line 226 of file [mutex.cpp](#).

19.21.2.3 bool Mutex::Claim_i (uint32_t u32WaitTimeMS_) [private]

Claim_i.

Abstracts out timed/non-timed mutex claim operations.

Parameters

<i>u32WaitTimeMS_</i> S_	Time in MS to wait, 0 for infinite
-----------------------------	------------------------------------

Returns

true on successful claim, false otherwise

Definition at line 120 of file [mutex.cpp](#).

19.21.2.4 void Mutex::Init (void)

Init.

Initialize a mutex object for use - must call this function before using the object.

Examples:

[lab5_mutexes/main.cpp](#).

Definition at line 109 of file [mutex.cpp](#).

19.21.2.5 void Mutex::Release ()

Release.

Release the mutex. When the mutex is released, another object can enter the mutex-protected region.

If there are Threads waiting for the [Mutex](#) to become available, then the highest priority [Thread](#) will be unblocked at this time and will claim the [Mutex](#) lock immediately - this may result in an immediate context switch, depending on relative priorities.

If the calling [Thread](#)'s priority was boosted as a result of priority inheritance, the [Thread](#)'s previous priority will also be restored at this time.

Note that if a [Mutex](#) is held recursively, it must be Release'd the same number of times that it was Claim'd before it will be available for use by another [Thread](#).

Examples:

[lab5_mutexes/main.cpp](#).

Definition at line 233 of file [mutex.cpp](#).

19.21.2.6 void Mutex::WakeMe (Thread * pOwner_)

WakeMe.

Wake a thread blocked on the mutex. This is an internal function used for implementing timed mutexes relying on timer callbacks. Since these do not have access to the private data of the mutex and its base classes, we have to wrap this as a public method - do not use this for any other purposes.

Parameters

<i>pOwner_</i>	Thread to unblock from this object.
----------------	---

Definition at line 79 of file [mutex.cpp](#).

19.21.2.7 uint8_t Mutex::WakeNext () [private]

WakeNext.

Wake the next thread waiting on the [Mutex](#).

Definition at line 88 of file [mutex.cpp](#).

The documentation for this class was generated from the following files:

- [/home/moslevin/mark3-source/embedded/kernel/public/mutex.h](#)
- [/home/moslevin/mark3-source/embedded/kernel/mutex.cpp](#)

19.22 Notify Class Reference

The [Notify](#) class is a blocking object type, that allows one or more threads to wait for an event to occur before resuming operation.

```
#include <notify.h>
```

Inheritance diagram for Notify:

Public Member Functions

- void [Init](#) (void)
Init.
- void [Signal](#) (void)
Signal.
- void [Wait](#) (bool *pbFlag_)
Wait.
- bool [Wait](#) (uint32_t u32WaitTimeMS_, bool *pbFlag_)
Wait.
- void [WakeMe](#) ([Thread](#) *pclChosenOne_)
WakeMe.

Additional Inherited Members

19.22.1 Detailed Description

The [Notify](#) class is a blocking object type, that allows one or more threads to wait for an event to occur before resuming operation.

Examples:

[lab10_notifications/main.cpp](#).

Definition at line 33 of file [notify.h](#).

19.22.2 Member Function Documentation

19.22.2.1 void Notify::Init (void)

Init.

Initialize the Notification object prior to use.

Examples:

[lab10_notifications/main.cpp](#).

Definition at line 67 of file [notify.cpp](#).

19.22.2.2 void Notify::Signal (void)

Signal.

Signal the notification object. This will cause the highest priority thread currently blocking on the object to wake. If no threads are currently blocked on the object, the call has no effect.

Examples:

[lab10_notifications/main.cpp](#).

Definition at line 73 of file [notify.cpp](#).

19.22.2.3 void Notify::Wait (bool * pbFlag_)

Wait.

Block the current thread, waiting for a signal on the object.

Parameters

<i>pbFlag_</i>	Flag set to false on block, and true upon wakeup.
----------------	---

Examples:

[lab10_notifications/main.cpp](#).

Definition at line 94 of file [notify.cpp](#).

19.22.2.4 bool Notify::Wait (uint32_t u32WaitTimeMS_, bool * pbFlag_)

Wait.

Block the current thread, waiting for a signal on the object.

Parameters

<i>u32WaitTimeMS_</i>	Time to wait for the notification event.
<i>pbFlag_</i>	Flag set to false on block, and true upon wakeup.

Returns

true on notification, false on timeout

Definition at line 111 of file [notify.cpp](#).

19.22.2.5 void Notify::WakeMe (Thread * pciChosenOne_)

WakeMe.

Wake the specified thread from its current blocking queue. Note that this is only public in order to be accessible from a timer callack.

Parameters

<code>pclChosenOne</code> ↔ —	Thread to wake up
----------------------------------	-----------------------------------

Definition at line 147 of file [notify.cpp](#).

The documentation for this class was generated from the following files:

- [/home/moslevin/mark3-source/embedded/kernel/public/notify.h](#)
- [/home/moslevin/mark3-source/embedded/kernel/notify.cpp](#)

19.23 PriorityMap Class Reference

The [PriorityMap](#) class.

```
#include <priomap.h>
```

Public Member Functions

- [PriorityMap](#) ()
PriorityMap.
- void [Set](#) ([PORT_PRIO_TYPE](#) uXPrio_)
Set Set the priority map bitmap data, at all levels, for the given priority.
- void [Clear](#) ([PORT_PRIO_TYPE](#) uXPrio_)
Clear Clear the priority map bitmap data, at all levels, for the given priority.
- [PORT_PRIO_TYPE](#) [HighestPriority](#) (void)
HighestPriority.

19.23.1 Detailed Description

The [PriorityMap](#) class.

Definition at line 70 of file [priomap.h](#).

19.23.2 Constructor & Destructor Documentation

19.23.2.1 [PriorityMap::PriorityMap](#) ()

[PriorityMap.](#)

Initialize the priority map object, clearing the bitamp data to all 0's.

Definition at line 51 of file [priomap.cpp](#).

19.23.3 Member Function Documentation

19.23.3.1 void [PriorityMap::Clear](#) ([PORT_PRIO_TYPE](#) uXPrio_)

Clear Clear the priority map bitmap data, at all levels, for the given priority.

Parameters

<code>uXPrio_</code>	Priority level to clear the bitmap data for.
----------------------	--

Definition at line 78 of file [priomap.cpp](#).

19.23.3.2 `PORT_PRIO_TYPE` `PriorityMap::HighestPriority (void)`

HighestPriority.

Computes the numeric priority of the highest-priority thread represented in the priority map.

Returns

Highest priority ready-thread's number.

Definition at line 94 of file [priomap.cpp](#).

19.23.3.3 `void` `PriorityMap::Set (PORT_PRIO_TYPE uXPrio_)`

Set Set the priority map bitmap data, at all levels, for the given priority.

Parameters

<code>uXPrio_</code>	Priority level to set the bitmap data for.
----------------------	--

Definition at line 64 of file [priomap.cpp](#).

The documentation for this class was generated from the following files:

- [/home/moslevin/mark3-source/embedded/kernel/public/priomap.h](#)
- [/home/moslevin/mark3-source/embedded/kernel/priomap.cpp](#)

19.24 Profiler Class Reference

System profiling timer interface.

```
#include <kernelprofile.h>
```

Static Public Member Functions

- static void [Init](#) ()
Init.
- static void [Start](#) ()
Start.
- static void [Stop](#) ()
Stop.
- static `PORT_TIMER_COUNT_TYPE` [Read](#) ()
Read.
- static void [Process](#) ()
Process.
- static uint32_t [GetEpoch](#) ()
GetEpoch.

19.24.1 Detailed Description

System profiling timer interface.

Definition at line 37 of file [kernelprofile.h](#).

19.24.2 Member Function Documentation

19.24.2.1 `static uint32_t Profiler::GetEpoch () [inline],[static]`

GetEpoch.

Return the current timer epoch

Definition at line 81 of file [kernelprofile.h](#).

19.24.2.2 `void Profiler::Init (void) [static]`

Init.

Initialize the global system profiler. Must be called prior to use.

Definition at line 32 of file [kernelprofile.cpp](#).

19.24.2.3 `void Profiler::Process (void) [static]`

Process.

Process the profiling counters from ISR.

Definition at line 70 of file [kernelprofile.cpp](#).

19.24.2.4 `PORT_TIMER_COUNT_TYPE Profiler::Read () [static]`

Read.

Read the current tick count in the timer.

Definition at line 58 of file [kernelprofile.cpp](#).

19.24.2.5 `void Profiler::Start (void) [static]`

Start.

Start the global profiling timer service.

Definition at line 42 of file [kernelprofile.cpp](#).

19.24.2.6 `void Profiler::Stop () [static]`

Stop.

Stop the global profiling timer service

Definition at line 51 of file [kernelprofile.cpp](#).

The documentation for this class was generated from the following files:

- [/home/moslevin/mark3-source/embedded/kernel/cpu/avr/atmega328p/gcc/public/kernelprofile.h](#)
- [/home/moslevin/mark3-source/embedded/kernel/cpu/avr/atmega328p/gcc/kernelprofile.cpp](#)

19.25 ProfileTimer Class Reference

Profiling timer.

```
#include <profile.h>
```

Public Member Functions

- void [Init](#) ()
Init.
- void [Start](#) ()
Start.
- void [Stop](#) ()
Stop.
- uint32_t [GetAverage](#) ()
GetAverage.
- uint32_t [GetCurrent](#) ()
GetCurrent.

Private Member Functions

- uint32_t [ComputeCurrentTicks](#) (uint16_t u16Count_, uint32_t u32Epoch_)
ComputeCurrentTicks.

Private Attributes

- uint32_t [m_u32Cumulative](#)
Cumulative tick-count for this timer.
- uint32_t [m_u32CurrentIteration](#)
Tick-count for the current iteration.
- uint16_t [m_u16Initial](#)
Initial count.
- uint32_t [m_u32InitialEpoch](#)
Initial Epoch.
- uint16_t [m_u16Iterations](#)
Number of iterations executed for this profiling timer.
- bool [m_bActive](#)
Whether or not the timer is active or stopped.

19.25.1 Detailed Description

Profiling timer.

This class is used to perform high-performance profiling of code to see how int32_t certain operations take. useful in instrumenting the performance of key algorithms and time-critical operations to ensure real-timer behavior.

Definition at line 69 of file [profile.h](#).

19.25.2 Member Function Documentation

19.25.2.1 uint32_t ProfileTimer::ComputeCurrentTicks (uint16_t u16Count_, uint32_t u32Epoch_) [private]

ComputeCurrentTicks.

Figure out how many ticks have elapsed in this iteration

Parameters

<i>u16Count_</i>	Current timer count
<i>u32Epoch_</i>	Current timer epoch

Returns

Current tick count

Definition at line 107 of file [profile.cpp](#).

19.25.2.2 uint32_t ProfileTimer::GetAverage ()

GetAverage.

Get the average time associated with this operation.

Returns

Average tick count normalized over all iterations

Definition at line 83 of file [profile.cpp](#).

19.25.2.3 uint32_t ProfileTimer::GetCurrent ()

GetCurrent.

Return the current tick count held by the profiler. Valid for both active and stopped timers.

Returns

The currently held tick count.

Definition at line 92 of file [profile.cpp](#).

19.25.2.4 void ProfileTimer::Init (void)

Init.

Initialize the profiling timer prior to use. Can also be used to reset a timer that's been used previously.

Definition at line 43 of file [profile.cpp](#).

19.25.2.5 void ProfileTimer::Start (void)

Start.

Start a profiling session, if the timer is not already active. Has no effect if the timer is already active.

Definition at line 52 of file [profile.cpp](#).

19.25.2.6 void ProfileTimer::Stop ()

Stop.

Stop the current profiling session, adding to the cumulative time for this timer, and the total iteration count.

Definition at line 65 of file [profile.cpp](#).

The documentation for this class was generated from the following files:

- </home/moslevin/mark3-source/embedded/kernel/profile.cpp>

19.26 Quantum Class Reference

Static-class used to implement [Thread](#) quantum functionality, which is a key part of round-robin scheduling.

```
#include <quantum.h>
```

Static Public Member Functions

- static void [UpdateTimer](#) ()
UpdateTimer.
- static void [AddThread](#) ([Thread](#) *pclThread_)
AddThread.
- static void [RemoveThread](#) ()
RemoveThread.
- static void [SetInTimer](#) (void)
SetInTimer.
- static void [ClearInTimer](#) (void)
ClearInTimer.

Static Private Member Functions

- static void [SetTimer](#) ([Thread](#) *pclThread_)
SetTimer.

19.26.1 Detailed Description

Static-class used to implement [Thread](#) quantum functionality, which is a key part of round-robin scheduling.

Definition at line [41](#) of file [quantum.h](#).

19.26.2 Member Function Documentation

19.26.2.1 void Quantum::AddThread (Thread * pclThread_) [static]

AddThread.

Add the thread to the quantum timer. Only one thread can own the quantum, since only one thread can be running on a core at a time.

Definition at line [86](#) of file [quantum.cpp](#).

19.26.2.2 static void Quantum::ClearInTimer (void) [inline],[static]

ClearInTimer.

Clear the flag once the timer callback function has been completed.

Definition at line [83](#) of file [quantum.h](#).

19.26.2.3 void Quantum::RemoveThread (void) [static]

RemoveThread.

Remove the thread from the quantum timer. This will cancel the timer.

Definition at line 111 of file [quantum.cpp](#).

19.26.2.4 static void Quantum::SetInTimer (void) [inline],[static]

SetInTimer.

Set a flag to indicate that the CPU is currently running within the timer-callback routine. This prevents the [Quantum](#) timer from being updated in the middle of a callback cycle, potentially resulting in the kernel timer becoming disabled.

Definition at line 77 of file [quantum.h](#).

19.26.2.5 void Quantum::SetTimer (Thread * *pcThread_*) [static],[private]

SetTimer.

Set up the quantum timer in the timer scheduler. This creates a one-shot timer, which calls a static callback in [quantum.cpp](#) that on expiry will pivot the head of the threadlist for the thread's priority. This is the mechanism that provides round-robin scheduling in the system.

Parameters

<i>pcThread_</i>	Pointer to the thread to set the Quantum timer on
------------------	---

Definition at line 76 of file [quantum.cpp](#).

19.26.2.6 void Quantum::UpdateTimer (void) [static]

UpdateTimer.

This function is called to update the thread quantum timer whenever something in the scheduler has changed. This can result in the timer being re-loaded or started. The timer is never stopped, but it may be ignored on expiry.

Definition at line 123 of file [quantum.cpp](#).

The documentation for this class was generated from the following files:

- [/home/moslevin/mark3-source/embedded/kernel/public/quantum.h](#)
- [/home/moslevin/mark3-source/embedded/kernel/quantum.cpp](#)

19.27 Scheduler Class Reference

Priority-based round-robin [Thread](#) scheduling, using ThreadLists for housekeeping.

```
#include <scheduler.h>
```

Static Public Member Functions

- static void [Init](#) ()
Init.
- static void [Schedule](#) ()
Schedule.
- static void [Add](#) ([Thread](#) **pcThread_*)

- Add.*
- static void [Remove](#) ([Thread](#) **pciThread_*)
- Remove.*
- static bool [SetScheduler](#) (bool *bEnable_*)
- SetScheduler.*
- static [Thread](#) * [GetCurrentThread](#) ()
- GetCurrentThread.*
- static volatile [Thread](#) * [GetNextThread](#) ()
- GetNextThread.*
- static [ThreadList](#) * [GetThreadList](#) ([PORT_PRIO_TYPE](#) *uXPriority_*)
- GetThreadList.*
- static [ThreadList](#) * [GetStopList](#) ()
- GetStopList.*
- static bool [IsEnabled](#) ()
- IsEnabled.*
- static void [QueueScheduler](#) ()
- QueueScheduler.*

Static Private Attributes

- static bool [m_bEnabled](#)
Scheduler's state - enabled or disabled.
- static bool [m_bQueuedSchedule](#)
Variable representing whether or not there's a queued scheduler operation.
- static [ThreadList](#) [m_clStopList](#)
ThreadList for all stopped threads.
- static [ThreadList](#) [m_aclPriorities](#) [[KERNEL_NUM_PRIORITIES](#)]
ThreadLists for all threads at all priorities.
- static [PriorityMap](#) [m_clPrioMap](#)
Priority bitmap lookup structure, 1-bit per thread priority.

19.27.1 Detailed Description

Priority-based round-robin [Thread](#) scheduling, using [ThreadLists](#) for housekeeping.

Definition at line 62 of file [scheduler.h](#).

19.27.2 Member Function Documentation

19.27.2.1 void Scheduler::Add ([Thread](#) * *pciThread_*) [static]

Add.

Add a thread to the scheduler at its current priority level.

Parameters

<i>pciThread_</i>	Pointer to the thread to add to the scheduler
-------------------	---

Definition at line 89 of file [scheduler.cpp](#).

19.27.2.2 `static Thread* Scheduler::GetCurrentThread () [inline],[static]`

GetCurrentThread.

Return the pointer to the currently-running thread.

Returns

Pointer to the currently-running thread

Examples:

[lab9_dynamic_threads/main.cpp](#).

Definition at line 121 of file [scheduler.h](#).

19.27.2.3 `static volatile Thread* Scheduler::GetNextThread () [inline],[static]`

GetNextThread.

Return the pointer to the thread that should run next, according to the last run of the scheduler.

Returns

Pointer to the next-running thread

Definition at line 130 of file [scheduler.h](#).

19.27.2.4 `static ThreadList* Scheduler::GetStopList () [inline],[static]`

GetStopList.

Return the pointer to the list of threads that are in the scheduler's stopped state.

Returns

Pointer to the [ThreadList](#) containing the stopped threads

Definition at line 150 of file [scheduler.h](#).

19.27.2.5 `static ThreadList* Scheduler::GetThreadList (PORT_PRIO_TYPE uXPriority_) [inline],[static]`

GetThreadList.

Return the pointer to the active list of threads that are at the given priority level in the scheduler.

Parameters

<i>uXPriority_</i>	Priority level of the threadlist
--------------------	----------------------------------

Returns

Pointer to the [ThreadList](#) for the given priority level

Definition at line 141 of file [scheduler.h](#).

19.27.2.6 `void Scheduler::Init (void) [static]`

Init.

Intiaillize the scheduler, must be called before use.

Definition at line 54 of file [scheduler.cpp](#).

19.27.2.7 `static bool Scheduler::IsEnabled () [inline],[static]`

IsEnabled.

Return the current state of the scheduler - whether or not scheduling is enabled or disabled.

Returns

true - scheduler enabled, false - disabled

Definition at line 159 of file [scheduler.h](#).

19.27.2.8 `static void Scheduler::QueueScheduler () [inline],[static]`

QueueScheduler.

Tell the kernel to perform a scheduling operation as soon as the scheduler is re-enabled.

Definition at line 166 of file [scheduler.h](#).

19.27.2.9 `void Scheduler::Remove (Thread * pclThread_) [static]`

Remove.

Remove a thread from the scheduler at its current priority level.

Parameters

<i>pclThread_</i>	Pointer to the thread to be removed from the scheduler
-------------------	--

Definition at line 95 of file [scheduler.cpp](#).

19.27.2.10 `void Scheduler::Schedule () [static]`

Schedule.

Run the scheduler, determines the next thread to run based on the current state of the threads. Note that the next-thread chosen from this function is only valid while in a critical section.

Definition at line 63 of file [scheduler.cpp](#).

19.27.2.11 `bool Scheduler::SetScheduler (bool bEnable_) [static]`

SetScheduler.

Set the active state of the scheduler. When the scheduler is disabled, the *next thread* is never set; the currently running thread will run forever until the scheduler is enabled again. Care must be taken to ensure that we don't end up trying to block while the scheduler is disabled, otherwise the system ends up in an unusable state.

Parameters

<i>bEnable_</i>	true to enable, false to disable the scheduler
-----------------	--

Definition at line 101 of file [scheduler.cpp](#).

The documentation for this class was generated from the following files:

- [/home/moslevin/mark3-source/embedded/kernel/public/scheduler.h](#)
- [/home/moslevin/mark3-source/embedded/kernel/scheduler.cpp](#)

19.28 Semaphore Class Reference

Binary & Counting semaphores, based on [BlockingObject](#) base class.

```
#include <ksemaphore.h>
```

Inheritance diagram for Semaphore:

Public Member Functions

- void [Init](#) (uint16_t u16InitVal_, uint16_t u16MaxVal_)
Initialize a semaphore before use.
- bool [Post](#) ()
Increment the semaphore count.
- void [Pend](#) ()
Decrement the semaphore count.
- uint16_t [GetCount](#) ()
Return the current semaphore counter.
- bool [Pend](#) (uint32_t u32WaitTimeMS_)
Decrement the semaphore count.
- void [WakeMe](#) ([Thread](#) *pclChosenOne_)
Wake a thread blocked on the semaphore.

Private Member Functions

- uint8_t [WakeNext](#) ()
Wake the next thread waiting on the semaphore.
- bool [Pend_i](#) (uint32_t u32WaitTimeMS_)
Pend_i.

Private Attributes

- uint16_t [m_u16Value](#)
Current count held by the semaphore.
- uint16_t [m_u16MaxValue](#)
Maximum count that can be held by this semaphore.

Additional Inherited Members

19.28.1 Detailed Description

Binary & Counting semaphores, based on [BlockingObject](#) base class.

Examples:

[buffalogger/main.cpp](#), [lab4_semaphores/main.cpp](#), [lab6_timers/main.cpp](#), and [lab9_dynamic_threads/main.cpp](#).↔

Definition at line 37 of file [ksemaphore.h](#).

19.28.2 Member Function Documentation

19.28.2.1 uint16_t Semaphore::GetCount ()

Return the current semaphore counter.

This can be used by a thread to bypass blocking on a semaphore - allowing it to do other things until a non-zero count is returned, instead of blocking until the semaphore is posted.

Returns

The current semaphore counter value.

Definition at line 234 of file [ksemaphore.cpp](#).

19.28.2.2 void Semaphore::Init (uint16_t u16InitVal_, uint16_t u16MaxVal_)

Initialize a semaphore before use.

Must be called before attempting post/pend operations on the object.

This initialization is required to configure the behavior of the semaphore with regards to the initial and maximum values held by the semaphore. By providing access to the raw initial and maximum count elements of the semaphore, these objects are able to be used as either counting or binary semaphores.

To configure a semaphore object for use as a binary semaphore, set values of 0 and 1 respectively for the initial/maximum value parameters.

Any other combination of values can be used to implement a counting semaphore.

Parameters

<i>u16InitVal_</i>	Initial value held by the semaphore
<i>u16MaxVal_</i>	Maximum value for the semaphore. Must be nonzero.

Examples:

[buffalogger/main.cpp](#), [lab4_semaphores/main.cpp](#), [lab6_timers/main.cpp](#), and [lab9_dynamic_threads/main.cpp](#).↵

Definition at line 108 of file [ksemaphore.cpp](#).

19.28.2.3 void Semaphore::Pend ()

Decrement the semaphore count.

If the count is zero, the calling [Thread](#) will block until the semaphore is posted, and the [Thread](#)'s priority is higher than that of any other [Thread](#) blocked on the object.

Examples:

[buffalogger/main.cpp](#), [lab4_semaphores/main.cpp](#), [lab6_timers/main.cpp](#), and [lab9_dynamic_threads/main.cpp](#).↵

Definition at line 216 of file [ksemaphore.cpp](#).

19.28.2.4 `bool Semaphore::Pend (uint32_t u32WaitTimeMS_)`

Decrement the semaphore count.

If the count is zero, the thread will block until the semaphore is pended. If the specified interval expires before the thread is unblocked, then the status is returned back to the user.

Returns

true - semaphore was acquired before the timeout false - timeout occurred before the semaphore was claimed.

Definition at line 227 of file [ksemaphore.cpp](#).

19.28.2.5 `bool Semaphore::Pend_i (uint32_t u32WaitTimeMS_) [private]`

Pend_i.

Internal function used to abstract timed and untimed semaphore pend operations.

Parameters

<code>u32WaitTimeMS_</code> <code>S_</code>	Time in MS to wait
--	--------------------

Returns

true on success, false on failure.

Definition at line 165 of file [ksemaphore.cpp](#).

19.28.2.6 `bool Semaphore::Post ()`

Increment the semaphore count.

If the semaphore count is zero at the time this is called, and there are threads blocked on the object, this will immediately unblock the highest-priority blocked [Thread](#).

Note that if the priority of that [Thread](#) is higher than the current thread's priority, a context switch will occur and control will be relinquished to that [Thread](#).

Returns

true if the semaphore was posted, false if the count is already maxed out.

Examples:

[buffalogger/main.cpp](#), [lab4_semaphores/main.cpp](#), [lab6_timers/main.cpp](#), and [lab9_dynamic_threads/main.cpp](#).

Definition at line 120 of file [ksemaphore.cpp](#).

19.28.2.7 `void Semaphore::WakeMe (Thread * pChosenOne_)`

Wake a thread blocked on the semaphore.

This is an internal function used for implementing timed semaphores relying on timer callbacks. Since these do not have access to the private data of the semaphore and its base classes, we have to wrap this as a public method - do not use this for any other purposes.

Definition at line 82 of file [ksemaphore.cpp](#).

19.28.2.8 `uint8_t Semaphore::WakeNext () [private]`

Wake the next thread waiting on the semaphore.

Used internally.

Definition at line 91 of file [ksemaphore.cpp](#).

The documentation for this class was generated from the following files:

- [/home/moslevin/mark3-source/embedded/kernel/public/ksemaphore.h](#)
- [/home/moslevin/mark3-source/embedded/kernel/ksemaphore.cpp](#)

19.29 Thread Class Reference

Object providing fundamental multitasking support in the kernel.

```
#include <thread.h>
```

Inheritance diagram for Thread:

Public Member Functions

- `void Init (K_WORD *pwStack_, uint16_t u16StackSize_, PORT_PRIO_TYPE uXPriority_, ThreadEntry_↵
t pfEntryPoint_, void *pvArg_)`
Init.
- `void Start ()`
Start.
- `void Stop ()`
Stop.
- `ThreadList * GetOwner (void)`
GetOwner.
- `ThreadList * GetCurrent (void)`
GetCurrent.
- `PORT_PRIO_TYPE GetPriority (void)`
GetPriority.
- `PORT_PRIO_TYPE GetCurPriority (void)`
GetCurPriority.
- `void SetQuantum (uint16_t u16Quantum_)`
SetQuantum.
- `uint16_t GetQuantum (void)`
GetQuantum.
- `void SetCurrent (ThreadList *pclNewList_)`
SetCurrent.
- `void SetOwner (ThreadList *pclNewList_)`
SetOwner.
- `void SetPriority (PORT_PRIO_TYPE uXPriority_)`
SetPriority.

- void [InheritPriority](#) ([PORT_PRIO_TYPE](#) uXPriority_)
InheritPriority.
- void [Exit](#) ()
Exit.
- void [SetID](#) (uint8_t u8ID_)
SetID.
- uint8_t [GetID](#) ()
GetID.
- uint16_t [GetStackSlack](#) ()
GetStackSlack.
- uint16_t [GetEventFlagMask](#) ()
GetEventFlagMask returns the thread's current event-flag mask, which is used in conjunction with the [EventFlag](#) blocking object type.
- void [SetEventFlagMask](#) (uint16_t u16Mask_)
SetEventFlagMask Sets the active event flag bitfield mask.
- void [SetEventFlagMode](#) ([EventFlagOperation_t](#) eMode_)
SetEventFlagMode Sets the active event flag operation mode.
- [EventFlagOperation_t](#) [GetEventFlagMode](#) ()
GetEventFlagMode Returns the thread's event flag's operating mode.
- [Timer](#) * [GetTimer](#) ()
Return a pointer to the thread's timer object.
- void [SetExpired](#) (bool bExpired_)
SetExpired.
- bool [GetExpired](#) ()
GetExpired.
- void [InitIdle](#) ()
InitIdle Initialize this [Thread](#) object as the [Kernel](#)'s idle thread.
- [ThreadState_t](#) [GetState](#) ()
GetState Returns the current state of the thread to the caller.
- void [SetState](#) ([ThreadState_t](#) eState_)
SetState Set the thread's state to a new value.

Static Public Member Functions

- static void [Sleep](#) (uint32_t u32TimeMs_)
Sleep.
- static void [USleep](#) (uint32_t u32TimeUs_)
USleep.
- static void [Yield](#) (void)
Yield.

Private Member Functions

- void [SetPriorityBase](#) ([PORT_PRIO_TYPE](#) uXPriority_)
SetPriorityBase.

Static Private Member Functions

- static void [ContextSwitchSWI](#) (void)
ContextSwitchSWI.

Private Attributes

- [K_WORD * m_pwStackTop](#)
Pointer to the top of the thread's stack.
- [K_WORD * m_pwStack](#)
Pointer to the thread's stack.
- [uint8_t m_u8ThreadID](#)
Thread ID.
- [PORT_PRIO_TYPE m_uXPriority](#)
Default priority of the thread.
- [PORT_PRIO_TYPE m_uXCurPriority](#)
Current priority of the thread (priority inheritance)
- [ThreadState_t m_eState](#)
Enum indicating the thread's current state.
- [uint16_t m_u16StackSize](#)
Size of the stack (in bytes)
- [ThreadList * m_pclCurrent](#)
Pointer to the thread-list where the thread currently resides.
- [ThreadList * m_pclOwner](#)
Pointer to the thread-list where the thread resides when active.
- [ThreadEntry_t m_pfEntryPoint](#)
The entry-point function called when the thread starts.
- [void * m_pvArg](#)
Pointer to the argument passed into the thread's entrypt.
- [uint16_t m_u16Quantum](#)
Thread quantum (in milliseconds)
- [uint16_t m_u16FlagMask](#)
Event-flag mask.
- [EventFlagOperation_t m_eFlagMode](#)
Event-flag mode.
- [Timer m_clTimer](#)
Timer used for blocking-object timeouts.
- [bool m_bExpired](#)
Indicate whether or not a blocking-object timeout has occurred.

Friends

- class **ThreadPort**

19.29.1 Detailed Description

Object providing fundamental multitasking support in the kernel.

Examples:

[buffalogger/main.cpp](#), [lab10_notifications/main.cpp](#), [lab11_mailboxes/main.cpp](#), [lab1_kernel_setup/main.cpp](#), [lab2_idle_function/main.cpp](#), [lab3_round_robin/main.cpp](#), [lab4_semaphores/main.cpp](#), [lab5_mutexes/main.cpp](#), [lab6_timers/main.cpp](#), [lab7_events/main.cpp](#), [lab8_messages/main.cpp](#), and [lab9_dynamic_threads/main.cpp](#).

Definition at line 60 of file [thread.h](#).

19.29.2 Member Function Documentation

19.29.2.1 void Thread::ContextSwitchSWI(void) [static], [private]

ContextSwitchSWI.

This code is used to trigger the context switch interrupt. Called whenever the kernel decides that it is necessary to swap out the current thread for the "next" thread.

Definition at line 441 of file [thread.cpp](#).

19.29.2.2 void Thread::Exit ()

Exit.

Remove the thread from being scheduled again. The thread is effectively destroyed when this occurs. This is extremely useful for cases where a thread encounters an unrecoverable error and needs to be restarted, or in the context of systems where threads need to be created and destroyed dynamically.

This must not be called on the idle thread.

Examples:

[lab9_dynamic_threads/main.cpp](#).

Definition at line 217 of file [thread.cpp](#).

19.29.2.3 PORT_PRIO_TYPE Thread::GetCurPriority(void) [inline]

GetCurPriority.

Return the priority of the current thread

Returns

Priority of the current thread

Definition at line 176 of file [thread.h](#).

19.29.2.4 ThreadList* Thread::GetCurrent(void) [inline]

GetCurrent.

Return the [ThreadList](#) where the thread is currently located

Returns

Pointer to the thread's current list

Definition at line 159 of file [thread.h](#).

19.29.2.5 uint16_t Thread::GetEventFlagMask () [inline]

GetEventFlagMask returns the thread's current event-flag mask, which is used in conjunction with the [EventFlag](#) blocking object type.

Returns

A copy of the thread's event flag mask

Definition at line 321 of file [thread.h](#).

19.29.2.6 EventFlagOperation_t Thread::GetEventFlagMode () [inline]

GetEventFlagMode Returns the thread's event flag's operating mode.

Returns

The thread's event flag mode.

Definition at line 337 of file [thread.h](#).

19.29.2.7 bool Thread::GetExpired ()

GetExpired.

Return the status of the most-recent blocking call on the thread.

Returns

true - call expired, false - call did not expire

Definition at line 485 of file [thread.cpp](#).

19.29.2.8 uint8_t Thread::GetID () [inline]

GetID.

Return the 8-bit ID corresponding to this thread.

Returns

[Thread](#)'s 8-bit ID, set by the user

Definition at line 298 of file [thread.h](#).

19.29.2.9 ThreadList* Thread::GetOwner (void) [inline]

GetOwner.

Return the [ThreadList](#) where the thread belongs when it's in the active/ready state in the scheduler.

Returns

Pointer to the [Thread](#)'s owner list

Definition at line 151 of file [thread.h](#).

19.29.2.10 PORT_PRIO_TYPE Thread::GetPriority (void) [inline]

GetPriority.

Return the priority of the current thread

Returns

Priority of the current thread

Definition at line 168 of file [thread.h](#).

19.29.2.11 `uint16_t Thread::GetQuantum (void)` `[inline]`

GetQuantum.

Get the thread's round-robin execution quantum.

Returns

The thread's quantum

Definition at line 193 of file [thread.h](#).

19.29.2.12 `uint16_t Thread::GetStackSlack ()`

GetStackSlack.

Performs a (somewhat lengthy) check on the thread stack to check the amount of stack margin (or "slack") remaining on the stack. If you're having problems with blowing your stack, you can run this function at points in your code during development to see what operations cause problems. Also useful during development as a tool to optimally size thread stacks.

Returns

The amount of slack (unused bytes) on the stack

ToDo : Reverse the logic for MCUs where stack grows UP instead of down

Examples:

[lab9_dynamic_threads/main.cpp](#).

Definition at line 329 of file [thread.cpp](#).

19.29.2.13 `ThreadState_t Thread::GetState ()` `[inline]`

GetState Returns the current state of the thread to the caller.

Can be used to determine whether or not a thread is ready (or running), stopped, or terminated/exit'd.

Returns

ThreadState_t representing the thread's current state

Examples:

[lab9_dynamic_threads/main.cpp](#).

Definition at line 381 of file [thread.h](#).

19.29.2.14 `void Thread::InheritPriority (PORT_PRIO_TYPE uXPriority_)`

InheritPriority.

Allow the thread to run at a different priority level (temporarily) for the purpose of avoiding priority inversions. This should only be called from within the implementation of blocking-objects.

Parameters

<i>uXPriority_</i>	New Priority to boost to.
--------------------	---------------------------

Definition at line 434 of file [thread.cpp](#).

19.29.2.15 `void Thread::Init (K_WORD * pwStack_, uint16_t u16StackSize_, PORT_PRIO_TYPE uXPriority_, ThreadEntry_t pfEntryPoint_, void * pvArg_)`

Init.

Initialize a thread prior to its use. Initialized threads are placed in the stopped state, and are not scheduled until the thread's start method has been invoked first.

Parameters

<i>pwStack_</i>	Pointer to the stack to use for the thread
<i>u16StackSize_</i>	Size of the stack (in bytes)
<i>uXPriority_</i>	Priority of the thread (0 = idle, 7 = max)
<i>pfEntryPoint_</i>	This is the function that gets called when the thread is started
<i>pvArg_</i>	Pointer to the argument passed into the thread's entrypoint function.

Examples:

[buffalogger/main.cpp](#), [lab10_notifications/main.cpp](#), [lab11_mailboxes/main.cpp](#), [lab1_kernel_setup/main.cpp](#), [lab2_idle_function/main.cpp](#), [lab3_round_robin/main.cpp](#), [lab4_semaphores/main.cpp](#), [lab5_mutexes/main.cpp](#), [lab6_timers/main.cpp](#), [lab7_events/main.cpp](#), [lab8_messages/main.cpp](#), and [lab9_dynamic_threads/main.cpp](#).

Definition at line 70 of file [thread.cpp](#).

19.29.2.16 `void Thread::InitIdle (void)`

InitIdle Initialize this [Thread](#) object as the [Kernel](#)'s idle thread.

There should only be one of these, maximum, in a given system.

Definition at line 493 of file [thread.cpp](#).

19.29.2.17 `void Thread::SetCurrent (ThreadList * pclNewList_) [inline]`

SetCurrent.

Set the thread's current to the specified thread list

Parameters

<i>pclNewList_</i>	Pointer to the threadlist to apply thread ownership
--------------------	---

Definition at line 203 of file [thread.h](#).

19.29.2.18 `void Thread::SetEventFlagMask (uint16_t u16Mask_) [inline]`

SetEventFlagMask Sets the active event flag bitfield mask.

Parameters

<i>u16Mask_</i>	
-----------------	--

Definition at line 326 of file [thread.h](#).

19.29.2.19 void Thread::SetEventFlagMode (EventFlagOperation_t *eMode_*) [inline]

SetEventFlagMode Sets the active event flag operation mode.

Parameters

<i>eMode_</i>	Event flag operation mode, defines the logical operator to apply to the event flag.
---------------	---

Definition at line 332 of file [thread.h](#).

19.29.2.20 void Thread::SetExpired (bool *bExpired_*)

SetExpired.

Set the status of the current blocking call on the thread.

Parameters

<i>bExpired_</i>	true - call expired, false - call did not expire
------------------	--

Definition at line 479 of file [thread.cpp](#).

19.29.2.21 void Thread::SetID (uint8_t *u8ID_*) [inline]

SetID.

Set an 8-bit ID to uniquely identify this thread.

Parameters

<i>u8ID_</i>	8-bit Thread ID, set by the user
--------------	--

Definition at line 290 of file [thread.h](#).

19.29.2.22 void Thread::SetOwner (ThreadList * *pclNewList_*) [inline]

SetOwner.

Set the thread's owner to the specified thread list

Parameters

<i>pclNewList_</i>	Pointer to the threadlist to apply thread ownership
--------------------	---

Definition at line 211 of file [thread.h](#).

19.29.2.23 void Thread::SetPriority (PORT_PRIO_TYPE *uXPriority_*)

SetPriority.

Set the priority of the [Thread](#) (running or otherwise) to a different level. This activity involves re-scheduling, and must be done so with due caution, as it may effect the determinism of the system.

This should *a/ways* be called from within a critical section to prevent system issues.

Parameters

<i>uXPriority_</i>	New priority of the thread
--------------------	----------------------------

Definition at line 395 of file [thread.cpp](#).

19.29.2.24 void Thread::SetPriorityBase (**PORT_PRIO_TYPE** *uXPriority_*) [private]

SetPriorityBase.

Parameters

<i>uXPriority_</i>	
--------------------	--

Definition at line 385 of file [thread.cpp](#).

19.29.2.25 void Thread::SetQuantum (**uint16_t** *u16Quantum_*) [inline]

SetQuantum.

Set the thread's round-robin execution quantum.

Parameters

<i>u16Quantum_</i>	Thread 's execution quantum (in milliseconds)
--------------------	---

Examples:

[lab3_round_robin/main.cpp](#).

Definition at line 185 of file [thread.h](#).

19.29.2.26 void Thread::SetState (**ThreadState_t** *eState_*) [inline]

SetState Set the thread's state to a new value.

This is only to be used by code within the kernel, and is not intended for use by an end-user.

Parameters

<i>eState_</i>	New thread state to set.
----------------	--------------------------

Definition at line 389 of file [thread.h](#).

19.29.2.27 void Thread::Sleep (**uint32_t** *u32TimeMs_*) [static]

Sleep.

Put the thread to sleep for the specified time (in milliseconds). Actual time slept may be longer (but not less than) the interval specified.

Parameters

<i>u32TimeMs_</i>	Time to sleep (in ms)
-------------------	-----------------------

Examples:

[buffalogger/main.cpp](#), [lab10_notifications/main.cpp](#), [lab11_mailboxes/main.cpp](#), [lab1_kernel_setup/main.cpp](#), [lab2_idle_function/main.cpp](#), [lab7_events/main.cpp](#), [lab8_messages/main.cpp](#), and [lab9_dynamic_threads/main.cpp](#).

Definition at line 284 of file [thread.cpp](#).

19.29.2.28 void Thread::Start (void)

Start.

Start the thread - remove it from the stopped list, add it to the scheduler's list of threads (at the thread's set priority), and continue along.

Examples:

[buffalogger/main.cpp](#), [lab10_notifications/main.cpp](#), [lab11_mailboxes/main.cpp](#), [lab1_kernel_setup/main.cpp](#), [lab2_idle_function/main.cpp](#), [lab3_round_robin/main.cpp](#), [lab4_semaphores/main.cpp](#), [lab5_mutexes/main.cpp](#), [lab6_timers/main.cpp](#), [lab7_events/main.cpp](#), [lab8_messages/main.cpp](#), and [lab9_dynamic_threads/main.cpp](#).

Definition at line 145 of file [thread.cpp](#).

19.29.2.29 void Thread::Stop ()

Stop.

Stop a thread that's actively scheduled without destroying its stacks. Stopped threads can be restarted using the [Start\(\)](#) API.

Definition at line 177 of file [thread.cpp](#).

19.29.2.30 void Thread::USleep (uint32_t u32TimeUs_) [static]

USleep.

Put the thread to sleep for the specified time (in microseconds). Actual time slept may be longer (but not less than) the interval specified.

Parameters

<i>u32TimeUs_</i>	Time to sleep (in microseconds)
-------------------	---------------------------------

Definition at line 306 of file [thread.cpp](#).

19.29.2.31 void Thread::Yield (void) [static]

Yield.

Yield the thread - this forces the system to call the scheduler and determine what thread should run next. This is typically used when threads are moved in and out of the scheduler.

Definition at line 360 of file [thread.cpp](#).

The documentation for this class was generated from the following files:

- [/home/moslevin/mark3-source/embedded/kernel/thread.cpp](#)

19.30 ThreadList Class Reference

This class is used for building thread-management facilities, such as schedulers, and blocking objects.

```
#include <threadlist.h>
```

Inheritance diagram for ThreadList:

Public Member Functions

- [ThreadList](#) ()
ThreadList.
- void [SetPriority](#) ([PORT_PRIO_TYPE](#) uXPriority_)
SetPriority.
- void [SetMapPointer](#) ([PriorityMap](#) *pclMap_)
SetMapPointer.
- void [Add](#) ([LinkListNode](#) *node_)
Add.
- void [Add](#) ([LinkListNode](#) *node_, [PriorityMap](#) *pclMap_, [PORT_PRIO_TYPE](#) uXPriority_)
Add.
- void [AddPriority](#) ([LinkListNode](#) *node_)
AddPriority.
- void [Remove](#) ([LinkListNode](#) *node_)
Remove.
- [Thread](#) * [HighestWaiter](#) ()
HighestWaiter.

Private Attributes

- [PORT_PRIO_TYPE](#) m_uXPriority
Priority of the threadlist.
- [PriorityMap](#) * m_pclMap
Pointer to the bitmap/flag to set when used for scheduling.

Additional Inherited Members

19.30.1 Detailed Description

This class is used for building thread-management facilities, such as schedulers, and blocking objects.

Definition at line 35 of file [threadlist.h](#).

19.30.2 Constructor & Destructor Documentation

19.30.2.1 ThreadList::ThreadList () [inline]

[ThreadList](#).

Default constructor - zero-initializes the data.

Definition at line 44 of file [threadlist.h](#).

19.30.3 Member Function Documentation

19.30.3.1 void ThreadList::Add (LinkListNode * node_)

Add.

Add a thread to the threadlist.

Parameters

<i>node_</i>	Pointer to the thread (link list node) to add to the list
--------------	---

Definition at line 52 of file [threadlist.cpp](#).

19.30.3.2 void ThreadList::Add (LinkListNode * node_, PriorityMap * pclMap_, PORT_PRIO_TYPE uXPriority_)

Add.

Add a thread to the threadlist, specifying the flag and priority at the same time.

Parameters

<i>node_</i>	Pointer to the thread to add (link list node)
<i>pclMap_</i>	Pointer to the bitmap flag to set (if used in a scheduler context), or NULL for non-scheduler.
<i>uXPriority_</i>	Priority of the threadlist

Definition at line 101 of file [threadlist.cpp](#).

19.30.3.3 void ThreadList::AddPriority (LinkListNode * node_)

AddPriority.

Add a thread to the list such that threads are ordered from highest to lowest priority from the head of the list.

Parameters

<i>node_</i>	Pointer to a thread to add to the list.
--------------	---

Definition at line 65 of file [threadlist.cpp](#).

19.30.3.4 Thread * ThreadList::HighestWaiter ()

HighestWaiter.

Return a pointer to the highest-priority thread in the thread-list.

Returns

Pointer to the highest-priority thread

Definition at line 124 of file [threadlist.cpp](#).

19.30.3.5 void ThreadList::Remove (LinkListNode * node_)

Remove.

Remove the specified thread from the threadlist

Parameters

<i>node_</i>	Pointer to the thread to remove
--------------	---------------------------------

Definition at line 111 of file [threadlist.cpp](#).

19.30.3.6 void ThreadList::SetMapPointer (PriorityMap * pclMap_)

SetMapPointer.

Set the pointer to a bitmap to use for this threadlist. Once again, only needed when the threadlist is being used for scheduling purposes.

Parameters

<i>pclMap_</i>	Pointer to the priority map object used to track this thread.
----------------	---

Definition at line 46 of file [threadlist.cpp](#).

19.30.3.7 void ThreadList::SetPriority (PORT_PRIO_TYPE uXPriority_)

SetPriority.

Set the priority of this threadlist (if used for a scheduler).

Parameters

<i>uXPriority_</i>	Priority level of the thread list
--------------------	-----------------------------------

Definition at line 40 of file [threadlist.cpp](#).

The documentation for this class was generated from the following files:

- [/home/moslevin/mark3-source/embedded/kernel/threadlist.cpp](#)

19.31 ThreadPort Class Reference

Class defining the architecture specific functions required by the kernel.

```
#include <threadport.h>
```

Static Public Member Functions

- static void [StartThreads](#) ()
StartThreads.

Static Private Member Functions

- static void [InitStack](#) (Thread *pstThread_)
InitStack.

Friends

- class **Thread**

19.31.1 Detailed Description

Class defining the architecture specific functions required by the kernel.

This is limited (at this point) to a function to start the scheduler, and a function to initialize the default stack-frame for a thread.

Definition at line 275 of file [threadport.h](#).

19.31.2 Member Function Documentation

19.31.2.1 `void ThreadPort::InitStack (Thread * pstThread_) [static],[private]`

InitStack.

Initialize the thread's stack.

Parameters

<i>pstThread_</i>	Pointer to the thread to initialize
-------------------	-------------------------------------

Definition at line 39 of file [threadport.cpp](#).

19.31.2.2 `void ThreadPort::StartThreads () [static]`

StartThreads.

Function to start the scheduler, initial threads, etc.

Definition at line 130 of file [threadport.cpp](#).

The documentation for this class was generated from the following files:

- [/home/moslevin/mark3-source/embedded/kernel/cpu/avr/atmega328p/gcc/public/threadport.h](#)
- [/home/moslevin/mark3-source/embedded/kernel/cpu/avr/atmega328p/gcc/threadport.cpp](#)

19.32 Timer Class Reference

Kernel-managed software timers.

```
#include <timer.h>
```

Inheritance diagram for Timer:

Public Member Functions

- [Timer](#) ()
Timer.
- void [Init](#) ()
Init.
- void [Start](#) (bool bRepeat_, uint32_t u32IntervalMs_, [TimerCallback_t](#) pfCallback_, void *pvData_)
Start.

- void [Start](#) (bool bRepeat_, uint32_t u32IntervalMs_, uint32_t u32ToleranceMs_, [TimerCallback_t](#) pf←
Callback_, void *pvData_)
Start.
- void [Start](#) ()
Start.
- void [Stop](#) ()
Stop.
- void [SetFlags](#) (uint8_t u8Flags_)
SetFlags.
- void [SetCallback](#) ([TimerCallback_t](#) pfCallback_)
SetCallback.
- void [SetData](#) (void *pvData_)
SetData.
- void [SetOwner](#) ([Thread](#) *pclOwner_)
SetOwner.
- void [SetIntervalTicks](#) (uint32_t u32Ticks_)
SetIntervalTicks.
- void [SetIntervalSeconds](#) (uint32_t u32Seconds_)
SetIntervalSeconds.
- uint32_t [GetInterval](#) ()
GetInterval.
- void [SetIntervalMSeconds](#) (uint32_t u32MSeconds_)
SetIntervalMSeconds.
- void [SetIntervalUSeconds](#) (uint32_t u32USeconds_)
SetIntervalUSeconds.
- void [SetTolerance](#) (uint32_t u32Ticks_)
SetTolerance.

Private Attributes

- uint8_t [m_u8Flags](#)
Flags for the timer, defining if the timer is one-shot or repeated.
- [TimerCallback_t](#) [m_pfCallback](#)
Pointer to the callback function.
- uint32_t [m_u32Interval](#)
Interval of the timer in timer ticks.
- uint32_t [m_u32TimeLeft](#)
Time remaining on the timer.
- uint32_t [m_u32TimerTolerance](#)
Maximum tolerance (usedd for timer harmonization)
- [Thread](#) * [m_pclOwner](#)
Pointer to the owner thread.
- void * [m_pvData](#)
Pointer to the callback data.

Friends

- class [TimerList](#)

Additional Inherited Members

19.32.1 Detailed Description

Kernel-managed software timers.

Kernel-managed timers, used to provide high-precision high-resolution delays. Functionality is useful to both user-code, and is used extensively within the kernel and its blocking objects to implement round-robin scheduling, thread sleep, and timeouts. Relies on a single hardware timer, which is multiplexed through the kernel.

Examples:

[lab6_timers/main.cpp](#).

Definition at line 108 of file [timer.h](#).

19.32.2 Constructor & Destructor Documentation

19.32.2.1 `Timer::Timer () [inline]`

[Timer](#).

Default Constructor - Do nothing. Allow the init call to perform the necessary object initialization prior to use.

Definition at line 118 of file [timer.h](#).

19.32.3 Member Function Documentation

19.32.3.1 `uint32_t Timer::GetInterval () [inline]`

GetInterval.

Return the timer's configured interval in ticks

Returns

[Timer](#) interval in ticks.

Definition at line 240 of file [timer.h](#).

19.32.3.2 `void Timer::Init (void) [inline]`

Init.

Re-initialize the [Timer](#) to default values.

Definition at line 124 of file [timer.h](#).

19.32.3.3 `void Timer::SetCallback (TimerCallback_t pfCallback_) [inline]`

SetCallback.

Define the callback function to be executed on expiry of the timer

Parameters

<i>pfCallback_</i>	Pointer to the callback function to call
--------------------	--

Definition at line 197 of file [timer.h](#).

19.32.3.4 void Timer::SetData (void * *pvData_*) [inline]

SetData.

Define a pointer to be sent to the timer callbacak on timer expiry

Parameters

<i>pvData_</i>	Pointer to data to pass as argument into the callback
----------------	---

Definition at line 205 of file [timer.h](#).

19.32.3.5 void Timer::SetFlags (uint8_t *u8Flags_*) [inline]

SetFlags.

Set the timer's flags based on the bits in the *u8Flags_* argument

Parameters

<i>u8Flags_</i>	Flags to assign to the timer object. TIMERLIST_FLAG_ONE_SHOT for a one-shot timer, 0 for a continuous timer.
-----------------	--

Definition at line 189 of file [timer.h](#).

19.32.3.6 void Timer::SetIntervalMSeconds (uint32_t *u32MSeconds_*)

SetIntervalMSeconds.

Set the timer expiry interval in milliseconds (platform agnostic)

Parameters

<i>u32MSeconds_</i>	Time in milliseconds
---------------------	----------------------

Definition at line 115 of file [timer.cpp](#).

19.32.3.7 void Timer::SetIntervalSeconds (uint32_t *u32Seconds_*)

SetIntervalSeconds.

! The next three cost u16 330 bytes of flash on AVR...

Set the timer expiry interval in seconds (platform agnostic)

Parameters

<i>u32Seconds_</i>	Time in seconds
--------------------	-----------------

Definition at line 109 of file [timer.cpp](#).

19.32.3.8 void Timer::SetIntervalTicks (uint32_t *u32Ticks_*)

SetIntervalTicks.

Set the timer expiry in system-ticks (platform specific!)

Parameters

<i>u32Ticks_</i>	Time in ticks
------------------	---------------

Definition at line 101 of file [timer.cpp](#).

19.32.3.9 void Timer::SetIntervalUSecods (uint32_t *u32USecods_*)

SetIntervalUSecods.

Set the timer expiry interval in microseconds (platform agnostic)

Parameters

<i>u32USecods_</i>	Time in microseconds
--------------------	----------------------

Definition at line 121 of file [timer.cpp](#).

19.32.3.10 void Timer::SetOwner (Thread * *pcOwner_*) [inline]

SetOwner.

Set the owner-thread of this timer object (all timers must be owned by a thread).

Parameters

<i>pcOwner_</i>	Owner thread of this timer object
-----------------	-----------------------------------

Definition at line 214 of file [timer.h](#).

19.32.3.11 void Timer::SetTolerance (uint32_t *u32Ticks_*)

SetTolerance.

Set the timer's maximum tolerance in order to synchronize timer processing with other timers in the system.

Parameters

<i>u32Ticks_</i>	Maximum tolerance in ticks
------------------	----------------------------

Definition at line 133 of file [timer.cpp](#).

19.32.3.12 void Timer::Start (bool *bRepeat_*, uint32_t *u32IntervalMs_*, TimerCallback_t *pfCallback_*, void * *pvData_*)

Start.

Start a timer using default ownership, using repeats as an option, and millisecond resolution.

Parameters

<i>bRepeat_</i>	0 - timer is one-shot. 1 - timer is repeating.
<i>u32IntervalMs_</i>	- Interval of the timer in milliseconds
<i>pfCallback_</i>	- Function to call on timer expiry
<i>pvData_</i>	- Data to pass into the callback function

Examples:

[lab6_timers/main.cpp](#).

Definition at line 48 of file [timer.cpp](#).

19.32.3.13 void Timer::Start (bool *bRepeat_*, uint32_t *u32IntervalMs_*, uint32_t *u32ToleranceMs_*, TimerCallback_t *pfCallback_*, void * *pvData_*)

Start.

Start a timer using default ownership, using repeats as an option, and millisecond resolution.

Parameters

<i>bRepeat_</i>	0 - timer is one-shot. 1 - timer is repeating.
<i>u32IntervalMs_</i>	- Interval of the timer in milliseconds
<i>u32ToleranceMs_</i>	- Allow the timer expiry to be delayed by an additional maximum time, in order to have as many timers expire at the same time as possible.
<i>pfCallback_</i>	- Function to call on timer expiry
<i>pvData_</i>	- Data to pass into the callback function

Definition at line 69 of file [timer.cpp](#).

19.32.3.14 void Timer::Start (void)

Start.

Start or restart a timer using parameters previously configured via calls to Start(<with args>), or via the a-la-carte parameter setter methods. This is especially useful for retriggering one-shot timers that have previously expired, using the timer's previous configuration.

Definition at line 81 of file [timer.cpp](#).

19.32.3.15 void Timer::Stop ()

Stop.

Stop a timer already in progress. Has no effect on timers that have already been stopped.

Definition at line 92 of file [timer.cpp](#).

The documentation for this class was generated from the following files:

- [/home/moslevin/mark3-source/embedded/kernel/public/timer.h](#)
- [/home/moslevin/mark3-source/embedded/kernel/timer.cpp](#)

19.33 TimerList Class Reference

[TimerList](#) class - a doubly-linked-list of timer objects.

```
#include <timerlist.h>
```

Inheritance diagram for TimerList:

Public Member Functions

- void [Init](#) ()
Init.
- void [Add](#) ([Timer](#) *pclListNode_)
Add.
- void [Remove](#) ([Timer](#) *pclListNode_)
Remove.
- void [Process](#) ()
Process.

Private Attributes

- uint32_t [m_u32NextWakeup](#)
The time (in system clock ticks) of the next wakeup event.
- bool [m_bTimerActive](#)
Whether or not the timer is active.

Additional Inherited Members

19.33.1 Detailed Description

[TimerList](#) class - a doubly-linked-list of timer objects.

Definition at line 37 of file [timerlist.h](#).

19.33.2 Member Function Documentation

19.33.2.1 void [TimerList::Add](#) ([Timer](#) * [pclListNode_](#))

Add.

Add a timer to the [TimerList](#).

Parameters

pclListNode_	Pointer to the Timer to Add
------------------------------	---

Definition at line 56 of file [timerlist.cpp](#).

19.33.2.2 void [TimerList::Init](#) (void)

Init.

Initialize the [TimerList](#) object. Must be called before using the object.

Definition at line 49 of file [timerlist.cpp](#).

19.33.2.3 void [TimerList::Process](#) (void)

Process.

Process all timers in the timerlist as a result of the timer expiring. This will select a new timer epoch based on the next timer to expire. ToDo - figure out if we need to deal with any overtime here.

Definition at line 119 of file [timerlist.cpp](#).

19.33.2.4 void TimerList::Remove (Timer * *pcListNode_*)

Remove.

Remove a timer from the [TimerList](#), cancelling its expiry.

Parameters

<i>pcListNode_</i>	Pointer to the Timer to remove
--------------------	--

Definition at line 102 of file [timerlist.cpp](#).

The documentation for this class was generated from the following files:

- [/home/moslevin/mark3-source/embedded/kernel/public/timerlist.h](#)
- [/home/moslevin/mark3-source/embedded/kernel/timerlist.cpp](#)

19.34 TimerScheduler Class Reference

"Static" Class used to interface a global [TimerList](#) with the rest of the kernel.

```
#include <timerscheduler.h>
```

Static Public Member Functions

- static void [Init](#) ()
Init.
- static void [Add](#) (Timer **pcListNode_*)
Add.
- static void [Remove](#) (Timer **pcListNode_*)
Remove.
- static void [Process](#) ()
Process.

Static Private Attributes

- static [TimerList](#) *m_clTimerList*
TimerList object manipulated by the *Timer Scheduler*.

19.34.1 Detailed Description

"Static" Class used to interface a global [TimerList](#) with the rest of the kernel.

Definition at line 38 of file [timerscheduler.h](#).

19.34.2 Member Function Documentation

19.34.2.1 static void TimerScheduler::Add (Timer * *pcListNode_*) [inline],[static]

Add.

Add a timer to the timer scheduler. Adding a timer implicitly starts the timer as well.

Parameters

<i>pcListNode_</i>	Pointer to the timer list node to add
--------------------	---------------------------------------

Definition at line 56 of file [timerscheduler.h](#).

19.34.2.2 `static void TimerScheduler::Init (void) [inline],[static]`

Init.

Initialize the timer scheduler. Must be called before any timer, or timer-derived functions are used.

Definition at line 47 of file [timerscheduler.h](#).

19.34.2.3 `static void TimerScheduler::Process (void) [inline],[static]`

Process.

This function must be called on timer expiry (from the timer's ISR context). This will result in all timers being updated based on the epoch that just elapsed. The next timer epoch is set based on the next [Timer](#) object to expire.

Definition at line 74 of file [timerscheduler.h](#).

19.34.2.4 `static void TimerScheduler::Remove (Timer * pcListNode_) [inline],[static]`

Remove.

Remove a timer from the timer scheduler. May implicitly stop the timer if this is the only active timer scheduled.

Parameters

<i>pcListNode_</i>	Pointer to the timer list node to remove
--------------------	--

Definition at line 65 of file [timerscheduler.h](#).

The documentation for this class was generated from the following files:

- [/home/moslevin/mark3-source/embedded/kernel/public/timerscheduler.h](#)
- [/home/moslevin/mark3-source/embedded/kernel/timerlist.cpp](#)

20.19 /home/moslevin/mark3-source/embedded/kernel/cpu/avr/atmega328p/gcc/public/portcfg.h File Reference

Mark3 Port Configuration.

Macros

- `#define AVR (1)`
Define a macro indicating the CPU architecture for which this port belongs.
- `#define K_WORD uint8_t`
Define types that map to the CPU Architecture's default data-word and address size.
- `#define K_ADDR uint16_t`
Size of an address (pointer size)
- `#define PORT_PRIO_TYPE uint8_t`
Set a base datatype used to represent each element of the scheduler's priority bitmap.
- `#define PORT_PRIO_MAP_WORD_SIZE (1)`
size of PORT_PRIO_TYPE in bytes
- `#define PORT_SYSTEM_FREQ ((uint32_t)16000000)`
Define the running CPU frequency.
- `#define PORT_TIMER_FREQ ((uint32_t)(PORT_SYSTEM_FREQ / 1000))`
Set the timer frequency.
- `#define PORT_TIMER_COUNT_TYPE uint16_t`
Define the native type corresponding to the kernel timer hardware's counter register.
- `#define PORT_MIN_TIMER_TICKS (0)`
Minimum number of timer ticks for any delay or sleep, required to ensure that a timer cannot be initialized to a negative value.

20.19.1 Detailed Description

Mark3 Port Configuration.

This file is used to configure the kernel for your specific target CPU in order to provide the optimal set of features for a given use case.

!! NOTE: This file must ONLY be included from [mark3cfg.h](#)

Definition in file [portcfg.h](#).

20.19.2 Macro Definition Documentation

20.19.2.1 `#define AVR (1)`

Define a macro indicating the CPU architecture for which this port belongs.

This may also be set by the toolchain, but that's not guaranteed.

Definition at line 34 of file [portcfg.h](#).

20.19.2.2 `#define K_WORD uint8_t`

Define types that map to the CPU Architecture's default data-word and address size.

Size of a data word

```

00033 #ifndef AVR
00034 # define AVR (1)
00035 #endif
00036
00041 #define K_WORD uint8_t
00042 #define K_ADDR uint16_t
00043
00044
00051 #define PORT_PRIO_TYPE uint8_t
00052 #define PORT_PRIO_MAP_WORD_SIZE (1)
00053
00054
00058 #if !defined(PORT_SYSTEM_FREQ)
00059 #define PORT_SYSTEM_FREQ ((uint32_t)16000000)
00060 #endif
00061
00069 #if KERNEL_TIMERS_TICKLESS
00070 #define PORT_TIMER_FREQ ((uint32_t)(PORT_SYSTEM_FREQ / 256))
00071 #else
00072 #define PORT_TIMER_FREQ ((uint32_t)(PORT_SYSTEM_FREQ / 1000))
00073 #endif
00074
00078 #define PORT_TIMER_COUNT_TYPE uint16_t
00079
00080
00084 #define PORT_MIN_TIMER_TICKS (0)
00085
00086 #endif // __PORTCFG_H__

```

20.21 /home/moslevin/mark3-source/embedded/kernel/cpu/avr/atmega328p/gcc/public/threadport.h File Reference

ATMega328p Multithreading support.

```

#include "kerneltypes.h"
#include "thread.h"
#include <avr/io.h>
#include <avr/interrupt.h>

```

Classes

- class [ThreadPort](#)
Class defining the architecture specific functions required by the kernel.

Macros

- #define [ASM](#)(x) asm volatile(x);
ASM Macro - simplify the use of ASM directive in C.
- #define [SR_](#) 0x3F
Status register define - map to 0x003F.
- #define [SPH_](#) 0x3E
Stack pointer define.
- #define [TOP_OF_STACK](#)(x, y) (uint8_t*)((uint16_t)x + (y - 1))
Macro to find the top of a stack given its size and top address.
- #define [PUSH_TO_STACK](#)(x, y)
Push a value y to the stack pointer x and decrement the stack pointer.
- #define [Thread_SaveContext](#)()
Save the context of the Thread.
- #define [Thread_RestoreContext](#)()
Restore the context of the Thread.
- #define [CS_ENTER](#)()

These macros must be used in pairs !

- `#define CS_EXIT()`
Exit critical section (restore status register)
- `#define ENABLE_INTS() ASM("sei");`
Initiate a contex switch without using the SWI.

Functions

- `uint8_t __mark3_clz8 (uint8_t in_)`

20.21.1 Detailed Description

ATMega328p Multithreading support.

Definition in file [threadport.h](#).

20.21.2 Macro Definition Documentation

20.21.2.1 `#define CS_ENTER()`

Value:

```
\
{
    \
    uint8_t __x = _SFR_IO8 (SR_);
    ASM("cli");
```

These macros *must* be used in pairs !

Enter critical section (copy status register, disable interrupts)

Examples:

[buffalogger/main.cpp](#), and [lab9_dynamic_threads/main.cpp](#).

Definition at line 245 of file [threadport.h](#).

20.21.3 Function Documentation

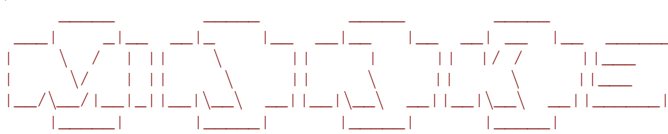

20.21.3.1 `uint8_t __mark3_clz8 (uint8_t in_) [inline]`

Lookup table based count-leading zeros implementation, used by scheduler by way of [PriorityMap](#)

Definition at line 51 of file [threadport.h](#).

20.22 threadport.h

#include "timerlist.h"
#include "quantum.h"
#include "kernel.h"
#include "kernelaware.h"
#include <avr/io.h>
#include <avr/interrupt.h>
```

Functions

- [ISR \(INT0_vect\) __attribute__\(\(signal](#)
[ISR\(INT0_vect\)](#) SWI using INT0 - used to trigger a context switch.
- [ISR \(TIMER1_COMPA_vect\)](#)
[ISR\(TIMER1_COMPA_vect\)](#) Timer interrupt ISR - causes a tick, which may cause a context switch.

20.23.1 Detailed Description

ATMega328p Multithreading.

Classes

- class [DevNull](#)

This class implements the "default" driver (/dev/null)

Functions

- static uint8_t [DrvCmp](#) (const char *szStr1_, const char *szStr2_)
DrvCmp.

Variables

- static [DevNull](#) cDevNull
Default driver included to allow for run-time "stubbing".

20.25.1 Detailed Description

Device driver/hardware abstraction layer.

Definition in file [driver.cpp](#).

20.25.2 Function Documentation

20.25.2.1 static uint8_t [DrvCmp](#) (const char * [szStr1_](#), const char * [szStr2_](#)) [static]

[DrvCmp.](#)

String comparison function used to compare input driver name against a known driver name in the existing driver list.

Parameters

szStr1_	user-specified driver name
szStr2_	name of a driver, provided from the driver table

Returns

1 on match, 0 on no-match

Definition at line 75 of file [driver.cpp](#).

20.26 driver.cpp

Classes

- union [KernelAwareData_t](#)

This structure is used to communicate between the kernel and a kernel- aware host.

Variables

- volatile bool [g_bIsKernelAware](#)

Will be set to true by a kernel-aware host.

- volatile uint8_t [g_u8KACommand](#)

Kernel-aware simulator command to execute.

- [KernelAwareData_t](#) [g_stKAData](#)

Data structure used to communicate with host.

20.31.1 Detailed Description

[Kernel](#) aware simulation support.

Definition in file [kernelaware.cpp](#).

20.31.2 Variable Documentation

20.31.2.1 volatile bool [g_bIsKernelAware](#)

Will be set to true by a kernel-aware host.

Definition at line 77 of file [kernelaware.cpp](#).

Data structure used to communicate with host.

TimedSemaphore_Callback.

20.33.1 Detailed Description

[Semaphore](#) Blocking-Object Implementation.

Definition in file [ksemaphore.cpp](#).

20.33.2 Function Documentation

20.33.2.1 void TimedSemaphore_Callback (Thread * pclOwner_, void * pvData_)

[TimedSemaphore_Callback.](#)

This function is called from the timer-expired context to trigger a timeout on this semaphore. This results in the waking of the thread that generated the semaphore pend call that was not completed in time.

Parameters

<i>pclOwner_</i>	Pointer to the thread to wake
<i>pvData_</i>	Pointer to the semaphore object that the thread is blocked on

Definition at line 56 of file [ksemaphore.cpp](#).

20.53 /home/moslevin/mark3-source/embedded/kernel/public/blocking.h File Reference

Blocking object base class declarations.

```
#include "kerneltypes.h"
#include "mark3cfg.h"
#include "ll.h"
#include "threadlist.h"
#include "thread.h"
```

Classes

- class [BlockingObject](#)

Class implementing thread-blocking primitives.

20.53.1 Detailed Description

Blocking object base class declarations.

A Blocking object in Mark3 is essentially a thread list. Any blocking object implementation (being a semaphore, mutex, event flag, etc.) can be built on top of this class, utilizing the provided functions to manipulate thread location within the [Kernel](#).

Blocking a thread results in that thread becoming de-scheduled, placed in the blocking object's own private list of threads which are waiting on the object.

Unblocking a thread results in the reverse: The thread is moved back to its original location from the blocking list.

The only difference between a blocking object based on this class is the logic used to determine what constitutes a Block or Unblock condition.

For instance, a semaphore Pend operation may result in a call to the Block() method with the currently-executing thread in order to make that thread wait for a semaphore Post. That operation would then invoke the Unblock() method, removing the blocking thread from the semaphore's list, and back into the appropriate thread inside the scheduler.

Care must be taken when implementing blocking objects to ensure that critical sections are used judiciously, otherwise asynchronous events like timers and interrupts could result in non-deterministic and often catastrophic behavior.

20.57 /home/moslevin/mark3-source/embedded/kernel/public/driver.h File Reference

[Driver](#) abstraction framework.

```
#include "kerneltypes.h"
#include "mark3cfg.h"
#include "ll.h"
```

Classes

- class [Driver](#)

Base device-driver class used in hardware abstraction.

- class [DriverList](#)

List of [Driver](#) objects used to keep track of all device drivers in the system.

20.57.1 Detailed Description

[Driver](#) abstraction framework.

[Driver](#) abstraction framework for Mark3C.

20.57.2 Intro

This is the basis of the driver framework. In the context of Mark3, drivers don't necessarily have to be based on physical hardware peripherals. They can be used to represent algorithms (such as random number generators), files, or protocol stacks. Unlike FunkOS, where driver IO is protected automatically by a mutex, we do not use this kind of protection - we leave it up to the driver implementor to do what's right in its own context. This also frees up the driver to implement all sorts of other neat stuff, like sending messages to threads associated with the driver. Drivers are implemented as character devices, with the standard array of posix-style accessor methods for reading, writing, and general driver control.

A global driver list is provided as a convenient and minimal "filesystem" structure, in which devices can be accessed by name.

20.57.3 Driver Design

A device driver needs to be able to perform the following operations: -Initialize a peripheral -Start/stop a peripheral -Handle I/O control operations -Perform various read/write operations

At the end of the day, that's pretty much all a device driver has to do, and all of the functionality that needs to be presented to the developer.

We abstract all device drivers using a base-class which implements the following methods: -Start/Open -Stop/Close -Control -Read -Write

A basic driver framework and API can thus be implemented in five function calls - that's it! You could even reduce that further by handling the initialize, start, and stop operations inside the "control" operation.

20.57.4 Driver API

In C++, we can implement this as a class to abstract these event handlers, with virtual void functions in the base class overridden by the inherited objects.

To add and remove device drivers from the global table, we use the following methods:

```
void DriverList::Add( Driver *pclDriver_ );
void DriverList::Remove( Driver *pclDriver_ );
```

`DriverList::Add()`/`Remove()` takes a single arguments the pointer to the object to operate on.

Once a driver has been added to the table, drivers are opened by NAME using `DriverList::FindByName("/dev/name")`. This function returns a pointer to the specified driver if successful, or to a built in /dev/null device if the path name is invalid. After a driver is open, that pointer is used for all other driver access functions.

This abstraction is incredibly useful any peripheral or service can be accessed through a consistent set of APIs, that make it easy to substitute implementations from one platform to another. Portability is ensured, the overhead is negligible, and it emphasizes the reuse of both driver and application code as separate entities.

Consider a system with drivers for I2C, SPI, and UART peripherals - under our driver framework, an application can initialize these peripherals and write a greeting to each using the same simple API functions for all drivers:

```
pclI2C = DriverList::FindByName("/dev/i2c");
pclUART = DriverList::FindByName("/dev/tty0");
pclSPI = DriverList::FindByName("/dev/spi");

pclI2C->Write(12, "Hello World!");
pclUART->Write(12, "Hello World!");
pclSPI->Write(12, "Hello World!");
```

20.67 /home/moslevin/mark3-source/embedded/kernel/public/kerneltypes.h File Reference

Basic data type primitives used throughout the OS.

```

#include <stdint.h>
#include <stdbool.h>
#include <stddef.h>

```

Typedefs

- typedef void(* [PanicFunc_t](#))(uint16_t u16PanicCode_)
Function pointer type used to implement kernel-panic handlers.
- typedef void(* [IdleFunc_t](#))(void)
Function pointer type used to implement the idle function, where support for an idle function (as opposed to an idle thread) exists.
- typedef void(* [ThreadEntry_t](#))(void *pvArg_)
Function pointer type used for thread entrypoint functions.

Enumerations

- enum [EventFlagOperation_t](#) {
 [EVENT_FLAG_ALL](#), [EVENT_FLAG_ANY](#), [EVENT_FLAG_ALL_CLEAR](#), [EVENT_FLAG_ANY_CLEAR](#),
 [EVENT_FLAG_MODES](#), [EVENT_FLAG_PENDING_UNBLOCK](#) }
This enumeration describes the different operations supported by the event flag blocking object.
- enum [ThreadState_t](#)
Enumeration representing the different states a thread can exist in.

20.67.1 Detailed Description

Basic data type primitives used throughout the OS.

Definition in file [kerneltypes.h](#).

20.67.2 Enumeration Type Documentation

20.67.2.1 enum EventFlagOperation_t

This enumeration describes the different operations supported by the event flag blocking object.

Enumerator

EVENT_FLAG_ALL Block until all bits in the specified bitmask are set.
EVENT_FLAG_ANY Block until any bits in the specified bitmask are set.
EVENT_FLAG_ALL_CLEAR Block until all bits in the specified bitmask are cleared.
EVENT_FLAG_ANY_CLEAR Block until any bits in the specified bitmask are cleared.
EVENT_FLAG_MODES Count of event-flag modes. Not used by user
EVENT_FLAG_PENDING_UNBLOCK Special code. Not used by user

20.71 /home/moslevin/mark3-source/embedded/kernel/public/ll.h File Reference

Core linked-list declarations, used by all kernel list types.

```
#include "kerneltypes.h"
```

Classes

- class [LinkedListNode](#)
Basic linked-list node data structure.
- class [LinkedList](#)
Abstract-data-type from which all other linked-lists are derived.
- class [DoubleLinkedList](#)
Doubly-linked-list data type, inherited from the base [LinkedList](#) type.
- class [CircularLinkedList](#)
Circular-linked-list data type, inherited from the base [LinkedList](#) type.

20.71.1 Detailed Description

Core linked-list declarations, used by all kernel list types.

At the heart of RTOS data structures are linked lists. Having a robust and efficient set of linked-list types that we can use as a foundation for building the rest of our kernel types allows u16 to keep our RTOS code efficient and logically-separated.

So what data types rely on these linked-list classes?

-Threads -ThreadLists -The [Scheduler](#) -Timers, -The [Timer Scheduler](#) -Blocking objects (Semaphores, Mutexes, etc...)

Pretty much everything in the kernel uses these linked lists. By having objects inherit from the base linked-list node type, we're able to leverage the double and circular linked-list classes to manager virtually every object type in the system without duplicating code. These functions are very efficient as well, allowing for very deterministic behavior in our code.

Mark3 [Kernel](#) Configuration.

```
#include "portcfg.h"
```

Macros

- [#define KERNEL_NUM_PRIORITIES](#) (8)
Define the number of thread priorities that the kernel's scheduler will support.
- [#define KERNEL_USE_TIMERS](#) (1)
The following options is related to all kernel time-tracking.
- [#define KERNEL_TIMERS_TICKLESS](#) (1)
If you've opted to use the kernel timers module, you have an option as to which timer implementation to use: Tick-based or Tick-less.
- [#define KERNEL_TIMERS_MINIMUM_DELAY_US](#) (25)
When using tickless timers, it is useful to define a minimum sleep value.
- [#define KERNEL_USE_TIMEOUTS](#) (1)
By default, if you opt to enable kernel timers, you also get timeout- enabled versions of the blocking object APIs along with it.
- [#define KERNEL_USE_QUANTUM](#) (1)
Do you want to enable time quanta? This is useful when you want to have tasks in the same priority group share time in a controlled way.
- [#define THREAD_QUANTUM_DEFAULT](#) (4)
This value defines the default thread quantum when KERNEL_USE_QUANTUM is enabled.
- [#define KERNEL_USE_NOTIFY](#) (1)
This is a simple blocking object, where a thread (or threads) are guaranteed to block until an asynchronous event signals the object.
- [#define KERNEL_USE_SEMAPHORE](#) (1)
Do you want the ability to use counting/binary semaphores for thread synchronization? Enabling this features provides fully-blocking semaphores and enables all API functions declared in semaphore.h.
- [#define KERNEL_USE_MUTEX](#) (1)
Do you want the ability to use mutual exclusion semaphores (mutex) for resource/block protection? Enabling this feature provides mutexes, with priority inheritance, as declared in [mutex.h](#).
- [#define KERNEL_USE_EVENTFLAG](#) (1)
Provides additional event-flag based blocking.
- [#define KERNEL_USE_MESSAGE](#) (1)

- Enable inter-thread messaging using message queues.*

 - #define [GLOBAL_MESSAGE_POOL_SIZE](#) (8)

If Messages are enabled, define the size of the default kernel message pool.
- #define [KERNEL_USE_MAILBOX](#) (1)

Enable inter-thread messaging using mailboxes.
- #define [KERNEL_USE_SLEEP](#) (1)

Do you want to be able to set threads to sleep for a specified time? This enables the [Thread::Sleep\(\)](#) API.
- #define [KERNEL_USE_DRIVER](#) (1)

Enabling device drivers provides a posix-like filesystem interface for peripheral device drivers.
- #define [KERNEL_USE_THREADNAME](#) (0)

Provide [Thread](#) method to allow the user to set a name for each thread in the system.
- #define [KERNEL_USE_DYNAMIC_THREADS](#) (1)

Provide extra [Thread](#) methods to allow the application to create (and more importantly destroy) threads at runtime.
- #define [KERNEL_USE_PROFILER](#) (1)

Provides extra classes for profiling the performance of code.
- #define [KERNEL_USE_DEBUG](#) (1)

Provides extra logic for kernel debugging, and instruments the kernel with extra asserts, and kernel trace functionality.
- #define [KERNEL_ENABLE_LOGGING](#) (0)

Set this to 1 to enable very chatty kernel logging.
- #define [KERNEL_ENABLE_USER_LOGGING](#) (1)

This enables a set of logging macros similar to the kernel-logging macros; however, these can be enabled or disabled independently.
- #define [KERNEL_USE_ATOMIC](#) (0)

Provides support for atomic operations, including addition, subtraction, set, and test-and-set.
- #define [SAFE_UNLINK](#) (0)

"Safe unlinking" performs extra checks on data to make sure that there are no consistencies when performing operations on linked lists.
- #define [KERNEL_AWARE_SIMULATION](#) (1)

Include support for kernel-aware simulation.
- #define [KERNEL_USE_IDLE_FUNC](#) (1)

Enabling this feature removes the necessity for the user to dedicate a complete thread for idle functionality.
- #define [KERNEL_USE_AUTO_ALLOC](#) (0)

This feature enables an additional set of APIs that allow for objects to be created on-the-fly out of a special heap, without having to explicitly allocate them (from stack, heap, or static memory).
- #define [KERNEL_USE_THREAD_CALLOUTS](#) (1)

This feature provides additional kernel APIs to register callout functions that are activated when threads are created or exited.
- #define [KERNEL_USE_STACK_GUARD](#) (0)

This feature, when enabled, tells the kernel to check whether any [Thread](#)'s stack has been exhausted (or slack falls below a certain safety threshold) before executing each context switch.

20.79.1 Detailed Description

Mark3 [Kernel](#) Configuration.

This file is used to configure the kernel for your specific application in order to provide the optimal set of features for a given use case.

Since you only pay the price (code space/RAM) for the features you use, you can usually find a sweet spot between features and resource usage by picking and choosing features a-la-carte. This config file is written in an "interactive" way, in order to minimize confusion about what each option provides, and to make dependencies obvious.

Definition in file [mark3cfg.h](#).

20.79.2 Macro Definition Documentation

20.79.2.1 `#define GLOBAL_MESSAGE_POOL_SIZE` (8)

If Messages are enabled, define the size of the default kernel message pool.

Messages can be manually added to the message pool, but this mechanism is more convenient and automatic. All message queues share their message objects from this global pool to maximize efficiency and simplify data management.

Definition at line 174 of file [mark3cfg.h](#).

20.79.2.2 `#define KERNEL_AWARE_SIMULATION` (1)

Include support for kernel-aware simulation.

Enabling this feature adds advanced profiling, trace, and environment-aware debugging and diagnostic functionality when Mark3-based applications are run on the flavr AVR simulator.

Definition at line 277 of file [mark3cfg.h](#).

20.79.2.3 `#define KERNEL_ENABLE_LOGGING` (0)

Set this to 1 to enable very chatty kernel logging.

Since most important things in the kernel emit logs, a large log-buffer and fast output are required in order to keep up. This is a pretty advanced power-user type feature, so it's disabled by default.

Definition at line 242 of file [mark3cfg.h](#).

20.79.2.4 `#define KERNEL_ENABLE_USER_LOGGING` (1)

This enables a set of logging macros similar to the kernel-logging macros; however, these can be enabled or disabled independently.

This allows for user-code to benefit from the built-in kernel logging macros without having to account for the super-high-volume of logs generated by kernel code. 1 to enable logging outside of kernel code

Definition at line 251 of file [mark3cfg.h](#).

20.79.2.5 `#define KERNEL_NUM_PRIORITIES` (8)

Define the number of thread priorities that the kernel's scheduler will support.

The number of thread priorities is limited only by the memory of the host CPU, as a [ThreadList](#) object is statically-allocated for each thread priority.

In practice, systems rarely need more than 32 priority levels, with the most complex having the capacity for 256.

Definition at line 41 of file [mark3cfg.h](#).

20.79.2.6 `#define KERNEL_TIMERS_MINIMUM_DELAY_US` (25)

When using tickless timers, it is useful to define a minimum sleep value.

In the event that a delay/sleep/timeout value lower than this is provided to a timer-based API, the minimum value will be substituted.

Definition at line 86 of file [mark3cfg.h](#).

20.79.2.7 `#define KERNEL_TIMERS_TICKLESS (1)`

If you've opted to use the kernel timers module, you have an option as to which timer implementation to use: Tick-based or Tick-less.

Tick-based timers provide a "traditional" RTOS timer implementation based on a fixed-frequency timer interrupt. While this provides very accurate, reliable timing, it also means that the CPU is being interrupted far more often than may be necessary (as not all timer ticks result in "real work" being done).

Tick-less timers still rely on a hardware timer interrupt, but uses a dynamic expiry interval to ensure that the interrupt is only called when the next timer expires. This increases the complexity of the timer interrupt handler, but reduces the number and frequency.

Note that the CPU port ([kerneltimer.cpp](#)) must be implemented for the particular timer variant desired.

Definition at line 77 of file [mark3cfg.h](#).

20.79.2.8 `#define KERNEL_USE_ATOMIC (0)`

Provides support for atomic operations, including addition, subtraction, set, and test-and-set.

Add/Sub/Set contain 8, 16, and 32-bit variants.

Definition at line 261 of file [mark3cfg.h](#).

20.79.2.9 `#define KERNEL_USE_AUTO_ALLOC (0)`

This feature enables an additional set of APIs that allow for objects to be created on-the-fly out of a special heap, without having to explicitly allocate them (from stack, heap, or static memory).

Note that auto-alloc memory cannot be reclaimed.

Definition at line 298 of file [mark3cfg.h](#).

20.79.2.10 `#define KERNEL_USE_DYNAMIC_THREADS (1)`

Provide extra [Thread](#) methods to allow the application to create (and more importantly destroy) threads at runtime. useful for designs implementing worker threads, or threads that can be restarted after encountering error conditions.

Definition at line 221 of file [mark3cfg.h](#).

20.79.2.11 `#define KERNEL_USE_EVENTFLAG (1)`

Provides additional event-flag based blocking.

This relies on an additional per-thread flag-mask to be allocated, which adds 2 bytes to the size of each thread object.

Definition at line 153 of file [mark3cfg.h](#).

20.79.2.12 `#define KERNEL_USE_IDLE_FUNC (1)`

Enabling this feature removes the necessity for the user to dedicate a complete thread for idle functionality.

This saves a full thread stack, but also requires a bit extra static data. This also adds a slight overhead to the context switch and scheduler, as a special case has to be taken into account.

Definition at line 287 of file [mark3cfg.h](#).

20.79.2.13 `#define KERNEL_USE_MAILBOX (1)`

Enable inter-thread messaging using mailboxes.

A mailbox manages a blob of data provided by the user, that is partitioned into fixed-size blocks called envelopes. The size of an envelope is set by the user when the mailbox is initialized. Any number of threads can read-from and write-to the mailbox. Envelopes can be sent-to or received-from the mailbox at the head or tail. In this way, mailboxes essentially act as a circular buffer that can be used as a blocking FIFO or LIFO queue.

Definition at line 187 of file [mark3cfg.h](#).

20.79.2.14 `#define KERNEL_USE_MESSAGE (1)`

Enable inter-thread messaging using message queues.

This is the preferred mechanism for IPC for serious multi-threaded communications; generally anywhere a semaphore or event-flag is insufficient.

Definition at line 161 of file [mark3cfg.h](#).

20.79.2.15 `#define KERNEL_USE_PROFILER (1)`

Provides extra classes for profiling the performance of code.

useful for debugging and development, but uses an additional hardware timer.

Definition at line 227 of file [mark3cfg.h](#).

20.79.2.16 `#define KERNEL_USE_QUANTUM (1)`

Do you want to enable time quanta? This is useful when you want to have tasks in the same priority group share time in a controlled way.

This allows equal tasks to use unequal amounts of the CPU, which is a great way to set up CPU budgets per thread in a round-robin scheduling system. If enabled, you can specify a number of ticks that serves as the default time period (quantum). Unless otherwise specified, every thread in a priority will get the default quantum.

Definition at line 116 of file [mark3cfg.h](#).

20.79.2.17 `#define KERNEL_USE_SEMAPHORE (1)`

Do you want the ability to use counting/binary semaphores for thread synchronization? Enabling this features provides fully-blocking semaphores and enables all API functions declared in semaphore.h.

If you have to pick one blocking mechanism, this is the one to choose.

Definition at line 139 of file [mark3cfg.h](#).

20.79.2.18 `#define KERNEL_USE_STACK_GUARD (0)`

This feature, when enabled, tells the kernel to check whether any [Thread](#)'s stack has been exhausted (or slack falls below a certain safety threshold) before executing each context switch.

Enabling this is the most effective means to guard against stack corruption and stack overflow in the kernel, at the cost of increased context switch latency.include CPU/Port specific configuration options

Definition at line 320 of file [mark3cfg.h](#).

20.79.2.19 #define KERNEL_USE_THREAD_CALLOUTS (1)

This feature provides additional kernel APIs to register callout functions that are activated when threads are created or exited.

This is useful for implementing low-level instrumentation based on information held in the threads.

Definition at line 310 of file [mark3cfg.h](#).

20.79.2.20 #define KERNEL_USE_THREADNAME (0)

Provide [Thread](#) method to allow the user to set a name for each thread in the system.

Adds a const char* pointer to the size of the thread object.

Definition at line 213 of file [mark3cfg.h](#).

20.79.2.21 #define KERNEL_USE_TIMEOUTS (1)

By default, if you opt to enable kernel timers, you also get timeout- enabled versions of the blocking object APIs along with it.

This support comes at a small cost to code size, but a slightly larger cost to realtime performance - as checking for the use of timers in the underlying internal code costs some cycles.

As a result, the option is given to the user here to manually disable these timeout-based APIs if desired by the user for performance and code-size reasons.

Definition at line 101 of file [mark3cfg.h](#).

20.79.2.22 #define KERNEL_USE_TIMERS (1)

The following options is related to all kernel time-tracking.

-timers provide a way for events to be periodically triggered in a lightweight manner. These can be periodic, or one-shot.

-Thread [Quantum](#) (usedd for round-robin scheduling) is dependent on this module, as is [Thread](#) Sleep functionality.

Definition at line 56 of file [mark3cfg.h](#).

20.79.2.23 #define SAFE_UNLINK (0)

"Safe unlinking" performs extra checks on data to make sure that there are no consistencies when performing operations on linked lists.

This goes beyond pointer checks, adding a layer of structural and metadata validation to help detect system corruption early.

Definition at line 269 of file [mark3cfg.h](#).

20.79.2.24 #define THREAD_QUANTUM_DEFAULT (4)

This value defines the default thread quantum when KERNEL_USE_QUANTUM is enabled.

The thread quantum value is in milliseconds

Inter-thread communication via message-passing.

```

#include "kerneltypes.h"
#include "mark3cfg.h"
#include "ll.h"
#include "ksemaphore.h"
#include "timerlist.h"

```

Classes

- class [Message](#)
Class to provide message-based IPC services in the kernel.
- class [MessagePool](#)
Implements a list of message objects.
- class [GlobalMessagePool](#)
Implements a list of message objects shared between all threads.
- class [MessageQueue](#)
List of messages, used as the channel for sending and receiving messages between threads.

20.81.1 Detailed Description

Inter-thread communication via message-passing.

Embedded systems guru Jack Ganssle once said that without a robust form of interprocess communications (IPC), an RTOS is just a toy. Mark3 implements a form of IPC to provide safe and flexible messaging between threads.

using kernel-managed IPC offers significant benefits over other forms of data sharing (i.e. Global variables) in that it avoids synchronization issues and race conditions common to the practice. using IPC also enforces a more disciplined coding style that keeps threads decoupled from one another and minimizes global data, preventing careless and hard-to-debug errors.

20.81.2 using Messages, Queues, and the Global Message Pool

```
// Declare a message queue shared between two threads
MessageQueue my_queue;

int main()
{
    ...
    // Initialize the message queue
    my_queue.init();
    ...
}

void Thread1()
{
    // Example TX thread - sends a message every 10ms
    while(1)
    {
        // Grab a message from the global message pool
        Message *tx_message = GlobalMessagePool::Pop();

        // Set the message data/parameters
        tx_message->SetCode( 1234 );
        tx_message->SetData( NULL );

        // Send the message on the queue.
        my_queue.Send( tx_message );
        Thread::Sleep(10);
    }
}

void Thread2()
{
    while()
    {
        // Blocking receive - wait until we have messages to process
        Message *rx_message = my_queue.Recv();

        // Do something with the message data...

        // Return back into the pool when done
        GlobalMessagePool::Push(rx_message);
    }
}
```

Mutual exclusion class declaration.

```

#include "kerneltypes.h"
#include "mark3cfg.h"
#include "blocking.h"
#include "timerlist.h"

```

Classes

- class [Mutex](#)

Mutual-exclusion locks, based on [BlockingObject](#).

20.83.1 Detailed Description

Mutual exclusion class declaration.

Resource locks are implemented using mutual exclusion semaphores ([Mutex_t](#)). Protected blocks can be placed around any resource that may only be accessed by one thread at a time. If additional threads attempt to access the protected resource, they will be placed in a wait queue until the resource becomes available. When the resource becomes available, the thread with the highest original priority claims the resource and is activated. Priority inheritance is included in the implementation to prevent priority inversion. Always ensure that you claim and release your mutex objects consistently, otherwise you may end up with a deadlock scenario that's hard to debug.

20.83.2 Initializing

Initializing a mutex object by calling:

```
clMutex.Init();
```

20.83.3 Resource protection example

```

clMutex.Claim();
...
<resource protected block>
...
clMutex.Release();

```

Classes

- class ProfileTimer

Profiling timer.

20.91.1 Detailed Description

High-precision profiling timers.

Enables the profiling and instrumentation of performance-critical code. Multiple timers can be used simultaneously to enable system-wide performance metrics to be computed in a lightweight manner.

Usage:

```

ProfileTimer clMyTimer;
int i;

clMyTimer.Init();

// Profile the same block of code ten times
for (i = 0; i < 10; i++)
{
    clMyTimer.Start();
    ...
    //Block of code to profile
    ...
    clMyTimer.Stop();
}

// Get the average execution time of all iterations
u32AverageTimer = clMyTimer.GetAverage();

// Get the execution time from the last iteration
u32LastTimer = clMyTimer.GetCurrent();

```

20.95 /home/moslevin/mark3-source/embedded/kernel/public/scheduler.h File Reference

[Thread](#) scheduler function declarations.

```

#include "kerneltypes.h"
#include "thread.h"
#include "threadport.h"
#include "priomap.h"

```

Classes

- class [Scheduler](#)
Priority-based round-robin [Thread](#) scheduling, using ThreadLists for housekeeping.

Variables

- volatile [Thread](#) * [g_pclNext](#)
Pointer to the currently-chosen next-running thread.
- [Thread](#) * [g_pclCurrent](#)
Pointer to the currently-running thread.

20.95.1 Detailed Description

[Thread](#) scheduler function declarations.

This scheduler implements a very flexible type of scheduling, which has become the defacto industry standard when it comes to real-time operating systems. This scheduling mechanism is referred to as priority round- robin.

From the name, there are two concepts involved here:

1) Priority scheduling:

Threads are each assigned a priority, and the thread with the highest priority which is ready to run gets to execute.

2) Round-robin scheduling:

Where there are multiple ready threads at the highest-priority level, each thread in that group gets to share time, ensuring that progress is made.

The scheduler uses an array of [ThreadList](#) objects to provide the necessary housekeeping required to keep track of threads at the various priorities. As a result, the scheduler contains one [ThreadList](#) per priority, with an additional list to manage the storage of threads which are in the "stopped" state (either have been stopped, or have not been started yet).

#include "priomap.h"
```

Classes

- class [Thread](#)

Object providing fundamental multitasking support in the kernel.

- struct [FakeThread_t](#)

If the kernel is set up to use an idle function instead of an idle thread, we use a placeholder data structure to "simulate" the effect of having an idle thread in the system.

20.97.1 Detailed Description

Platform independent thread class declarations.

Threads are an atomic unit of execution, and each instance of the thread class represents an instance of a program running on the processor. The [Thread](#) is the fundamental user-facing object in the kernel - it is what makes multiprocessing possible from application code.

In Mark3, threads each have their own context - consisting of a stack, and all of the registers required to multiplex a processor between multiple threads.

The [Thread](#) class inherits directly from the [LinkListNode](#) class to facilitate efficient thread management using Double, or Double-Circular linked lists.

20.101.2 Macro Definition Documentation

20.101.2.1 #define [TIMERLIST_FLAG_EXPIRED](#) (0x08)

[Timer](#) is actually expired.

Definition at line 36 of file [timer.h](#).

20.101.3 Typedef Documentation

20.101.3.1 typedef void(* TimerCallback_t)(Thread *pclOwner_, void *pvData_)

This type defines the callback function type for timer events.

Since these are called from an interrupt context, they do not operate from within a thread or object context directly – as a result, the context must be manually passed into the calls.

pclOwner_ is a pointer to the thread that owns the timer pvData_ is a pointer to some data or object that needs to know about the timer's expiry from within the timer interrupt context.

Definition at line 91 of file [timer.h](#).

Classes

- class [TimerList](#)

TimerList class - a doubly-linked-list of timer objects.

20.103.1 Detailed Description

Timer list declarations.

These classes implements a linked list of timer objects attached to the global kernel timer scheduler.

Definition in file [timerlist.h](#).

20.125.1 Detailed Description

Header providing C-language API bindings for the Mark3 kernel.

Definition in file [mark3c.h](#).

20.125.2 Function Documentation

20.125.2.1 EventFlag_t Alloc_EventFlag (void)

Alloc_EventFlag.

See also

EventFlag* AutoAlloc::NewEventFlag()

Returns

Handle to an allocated object, or NULL if heap exhausted

20.125.2.2 Mailbox_t Alloc_Mailbox (void)

Alloc_Mailbox.

See also

Mailbox* AutoAlloc::NewMailbox()

Returns

Handle to an allocated object, or NULL if heap exhausted

20.125.2.3 Message_t Alloc_Message (void)

Alloc_Message.

See also

AutoAlloc::NewMessage()

Returns

Handle to an allocated object, or NULL if heap exhausted

20.125.2.4 MessageQueue_t Alloc_MessageQueue (void)

Alloc_MessageQueue.

See also

MessageQueue* AutoAlloc::NewMessageQueue()

Returns

Handle to an allocated object, or NULL if heap exhausted

20.125.2.5 **Mutex_t** Alloc_Mutex (void)

Alloc_Mutex.

See also

Mutex* AutoAlloc::NewMutex()

Returns

Handle to an allocated object, or NULL if heap exhausted

20.125.2.6 **Notify_t** Alloc_Notify (void)

Alloc_Notify.

See also

Notify* AutoAlloc::NewNotify()

Returns

Handle to an allocated object, or NULL if heap exhausted

20.125.2.7 **Semaphore_t** Alloc_Semaphore (void)

Alloc_Semaphore.

See also

Semaphore* AutoAlloc::NewSemaphore()

Returns

Handle to an allocated object, or NULL if heap exhausted

20.125.2.8 **Thread_t** Alloc_Thread (void)

Alloc_Thread.

See also

Thread* AutoAlloc::NewThread()

Returns

Handle to an allocated object, or NULL if heap exhausted

20.125.2.9 **Timer_t** Alloc_Timer (void)

Alloc_Timer.

See also

Timer* AutoAlloc::NewTimer()

Returns

Handle to an allocated object, or NULL if heap exhausted

20.125.2.10 `void* AutoAlloc (uint16_t u16Size_)`

AutoAlloc.

See also

`void* AutoAlloc::Allocate(uint16_t u16Size_)`

Parameters

<i>u16Size_</i>	Size in bytes to allocate from the one-time-allocate heap
-----------------	---

Returns

Pointer to an allocated blob of memory, or NULL if heap exhausted

20.125.2.11 `void EventFlag_Clear (EventFlag_t handle, uint16_t u16Mask_)`

EventFlag_Clear.

See also

`void EventFlag::Clear(uint16_t u16Mask_)`

Parameters

<i>handle</i>	Handle of the event flag object
<i>u16Mask_</i>	Bits to clear in the eventflag's internal condition register

20.125.2.12 `uint16_t EventFlag_GetMask (EventFlag_t handle)`

EventFlag_GetMask.

See also

`void EventFlag::GetMask()`

Parameters

<i>handle</i>	Handle of the event flag object
---------------	---------------------------------

Returns

Return the current bitmask

20.125.2.13 `void EventFlag_Init (EventFlag_t handle)`

EventFlag_Init.

See also

`void EventFlag::Init()`

Parameters

<i>handle</i>	Handle of the event flag object
---------------	---------------------------------

20.125.2.14 void EventFlag_Set (EventFlag_t *handle*, uint16_t *u16Mask_*)

EventFlag_Set.

See also

void [EventFlag::Set\(uint16_t u16Mask_\)](#)

Parameters

<i>handle</i>	Handle of the event flag object
<i>u16Mask_</i>	Bits to set in the eventflag's internal condition register

20.125.2.15 uint16_t EventFlag_TimedWait (EventFlag_t *handle*, uint16_t *u16Mask_*, EventFlagOperation_t *eMode_*, uint32_t *u32TimeMS_*)

EventFlag_TimedWait.

See also

uint16_t [EventFlag::Wait\(uint16_t u16Mask_, EventFlagOperation_t eMode_, uint32_t u32TimeMS_\)](#)

Parameters

<i>handle</i>	Handle of the event flag object
<i>u16Mask_</i>	condition flags to wait for
<i>eMode_</i>	Specify conditions under which the thread will be unblocked
<i>u32TimeMS_</i>	Time in ms to wait before aborting the operation

Returns

bitfield contained in the eventflag on unblock, or 0 on expiry.

20.125.2.16 uint16_t EventFlag_Wait (EventFlag_t *handle*, uint16_t *u16Mask_*, EventFlagOperation_t *eMode_*)

EventFlag_Wait.

See also

uint16_t [EventFlag::Wait\(uint16_t u16Mask_, EventFlagOperation_t eMode_\)](#)

Parameters

<i>handle</i>	Handle of the event flag object
<i>u16Mask_</i>	condition flags to wait for
<i>eMode_</i>	Specify conditions under which the thread will be unblocked

Returns

bitfield contained in the eventflag on unblock

20.125.2.17 `Message_t GlobalMessagePool_Pop (void)`

`GlobalMessagePool_Pop`.

See also

[Message_t GlobalMessagePool::Pop\(\)](#)

Returns

Pointer to a [Message](#) object

20.125.2.18 `void GlobalMessagePool_Push (Message_t handle)`

`GlobalMessagePool_Push`.

See also

`void` [GlobalMessagePool::Push\(\)](#)

Parameters

<i>handle</i>	Handle of the message object
---------------	------------------------------

20.125.2.19 `thread_context_callout_t Kernel_GetThreadContextSwitchCallout (void)`

`Kernel_GetThreadContextSwitchCallout`.

See also

[Kernel::GetThreadContextSwitchCallout](#)

Returns

Current function called on each context switch

20.125.2.20 `thread_create_callout_t Kernel_GetThreadCreateCallout (void)`

`Kernel_GetThreadCreateCallout`.

See also

[Kernel::GetThreadCreateCallout](#)

Returns

Current function called on each thread creation

20.125.2.21 `thread_exit_callout_t Kernel_GetThreadExitCallout (void)`

`Kernel_GetThreadExitCallout`.

See also

[Kernel::GetThreadExitCallout](#)

Returns

Current function called on each thread exit

20.125.2.22 void Kernel_Init (void)

Kernel_Init.

See also

void [Kernel::Init\(\)](#)

20.125.2.23 bool Kernel_IsPanic (void)

Kernel_IsPanic.

See also

bool [Kernel::IsPanic\(\)](#)

Returns

Whether or not the kernel is in a panic state

20.125.2.24 bool Kernel_IsStarted (void)

Kernel_IsStarted.

See also

bool [Kernel::IsStarted\(\)](#)

Returns

Whether or not the kernel has started - true = running, false = not started

20.125.2.25 void Kernel_Panic (uint16_t u16Cause_)

Kernel_Panic.

See also

void [Kernel::Panic\(uint16_t u16Cause_\)](#)

Parameters

<i>u16Cause_</i>	Reason for the kernel panic
------------------	-----------------------------

20.125.2.26 void Kernel_SetIdleFunc (IdleFunc_t pIdle_)

Kernel_SetIdleFunc.

See also

void [Kernel::SetIdleFunc\(IdleFunc_t pIdle_\)](#)

Parameters

<i>pfIdle_</i>	Pointer to the idle function
----------------	------------------------------

20.125.2.27 void Kernel_SetPanic (PanicFunc_t *pfPanic_*)

Kernel_SetPanic.

See also

void [Kernel::SetPanic\(PanicFunc_t pfPanic_\)](#)

Parameters

<i>pfPanic_</i>	Panic function pointer
-----------------	------------------------

20.125.2.28 void Kernel_SetThreadContextSwitchCallout (thread_context_callout_t *pfContext_*)

Kernel_SetThreadContextSwitchCallout.

See also

[Kernel::SetThreadContextSwitchCallout](#)

Parameters

<i>pfContext_</i>	Function to call prior to each context switch
-------------------	---

20.125.2.29 void Kernel_SetThreadCreateCallout (thread_create_callout_t *pfCreate_*)

Kernel_SetThreadCreateCallout.

See also

[Kernel::SetThreadCreateCallout](#)

Parameters

<i>pfCreate_</i>	Function to call on thread creation
------------------	-------------------------------------

20.125.2.30 void Kernel_SetThreadExitCallout (thread_exit_callout_t *pfExit_*)

Kernel_SetThreadExitCallout.

See also

[Kernel::SetThreadExitCallout](#)

Parameters

<i>pfExit_</i>	Function to call on thread exit
----------------	---------------------------------

20.125.2.31 void Kernel_Start (void)

Kernel_Start.

See also

void [Kernel::Start\(\)](#)

20.125.2.32 void KernelAware_ExitSimulator (void)

KernelAware_ExitSimulator.

See also

void [KernelAware::ExitSimulator\(\)](#)

20.125.2.33 bool KernelAware_IsSimulatorAware (void)

KernelAware_IsSimulatorAware.

See also

void [Kernel::IsSimulatorAware\(\)](#)

Returns

true if the runtime environment/simulator is aware that it is running the Mark3 kernel.

20.125.2.34 void KernelAware_Print (const char * *szStr_*)

KernelAware_Print.

See also

void [KernelAware::Print\(const char *szStr_\)](#)

Parameters

<i>szStr_</i>	String to print to the kernel-aware simulator
---------------	---

20.125.2.35 void KernelAware_ProfileInit (const char * *szStr_*)

KernelAware_ProfileInit.

See also

void [KernelAware::ProfileInit\(const char *szStr_\)](#);

Parameters

<i>szStr_</i>	String to use as a tag for the profiling session.
---------------	---

20.125.2.36 void KernelAware_ProfileReport (void)

KernelAware_ProfileReport.

See also

void [KernelAware::ProfileReport\(\)](#)

20.125.2.37 void KernelAware_ProfileStart (void)

KernelAware_ProfileStart.

See also

void [KernelAware::ProfileStart\(\)](#)

20.125.2.38 void KernelAware_ProfileStop (void)

KernelAware_ProfileStop.

See also

void [KernelAware::ProfileStop\(\)](#)

20.125.2.39 void KernelAware_Trace (uint16_t *u16File_*, uint16_t *u16Line_*)

KernelAware_Trace.

See also

void [KernelAware::Trace\(uint16_t u16File_, uint16_t u16Line_\)](#);

Parameters

<i>u16File_</i>	16-bit code representing the file
<i>u16Line_</i>	16-bit code representing the line in the file

20.125.2.40 void KernelAware_Trace1 (uint16_t *u16File_*, uint16_t *u16Line_*, uint16_t *u16Arg1_*)

KernelAware_Trace1.

See also

void [KernelAware::Trace\(uint16_t u16File_, uint16_t u16Line_, uint16_t u16Arg1_\)](#);

Parameters

<i>u16File_</i>	16-bit code representing the file
<i>u16Line_</i>	16-bit code representing the line in the file
<i>u16Arg1_</i>	16-bit argument to the format string.

20.125.2.41 `void KernelAware_Trace2 (uint16_t u16File_, uint16_t u16Line_, uint16_t u16Arg1_, uint16_t u16Arg2_)`

KernelAware_Trace2.

See also

`void KernelAware::Trace(uint16_t u16File_, uint16_t u16Line_, uint16_t u16Arg1_, uint16_t u16Arg2_);`

Parameters

<i>u16File_</i>	16-bit code representing the file
<i>u16Line_</i>	16-bit code representing the line in the file
<i>u16Arg1_</i>	16-bit argument to the format string.
<i>u16Arg2_</i>	16-bit argument to the format string.

20.125.2.42 `uint16_t Mailbox_GetFreeSlots (Mailbox_t handle)`

Mailbox_GetFreeSlots.

See also

`uint16_t Mailbox::GetFreeSlots()`

Parameters

<i>handle</i>	Handle of the mailbox object
---------------	------------------------------

Returns

Number of free slots in the mailbox

20.125.2.43 `void Mailbox_Init (Mailbox_t handle, void * pvBuffer_, uint16_t u16BufferSize_, uint16_t u16ElementSize_)`

Mailbox_Init.

See also

`void Mailbox::Init(void *pvBuffer_, uint16_t u16BufferSize_, uint16_t u16ElementSize_)`

Parameters

<i>handle</i>	Handle of the mailbox object
<i>pvBuffer_</i>	Pointer to the static buffer to use for the mailbox
<i>u16BufferSize_</i>	Size of the mailbox buffer, in bytes
<i>u16ElementSize_</i>	Size of the mailbox element, in bytes

<i>u16ElementSize</i>	Size of each envelope, in bytes
-----------------------	---------------------------------

20.125.2.44 **bool Mailbox_IsEmpty (Mailbox_t handle)**

Mailbox_IsEmpty.

See also

bool Mailbox::IsEmpty()

Parameters

<i>handle</i>	Handle of the mailbox object
---------------	------------------------------

Returns

true if the mailbox is empty, false otherwise

20.125.2.45 **bool Mailbox_IsFull (Mailbox_t handle)**

Mailbox_IsFull.

See also

bool Mailbox::IsFull()

Parameters

<i>handle</i>	Handle of the mailbox object
---------------	------------------------------

Returns

true if the mailbox is full, false otherwise

20.125.2.46 **void Mailbox_Receive (Mailbox_t handle, void * pvData_)**

Mailbox_Receive.

See also

void [Mailbox::Receive\(void *pvData_\)](#)

Parameters

<i>handle</i>	Handle of the mailbox object
<i>pvData_</i>	Pointer to a buffer that will have the envelope's contents copied into upon delivery.

20.125.2.47 **void Mailbox_ReceiveTail (Mailbox_t handle, void * pvData_)**

Mailbox_ReceiveTail.

See also

void [Mailbox::ReceiveTail\(void *pvData_\)](#)

Parameters

<i>handle</i>	Handle of the mailbox object
<i>pvData_</i>	Pointer to a buffer that will have the envelope's contents copied into upon delivery.

20.125.2.48 `bool Mailbox_Send (Mailbox_t handle, void * pvData_)`

Mailbox_Send.

See also

bool [Mailbox::Send\(void *pvData_\)](#)

Parameters

<i>handle</i>	Handle of the mailbox object
<i>pvData_</i>	Pointer to the data object to send to the mailbox.

Returns

true - envelope was delivered, false - mailbox is full.

20.125.2.49 `bool Mailbox_SendTail (Mailbox_t handle, void * pvData_)`

Mailbox_SendTail.

See also

bool [Mailbox::SendTail\(void *pvData_\)](#)

Parameters

<i>handle</i>	Handle of the mailbox object
<i>pvData_</i>	Pointer to the data object to send to the mailbox.

Returns

true - envelope was delivered, false - mailbox is full.

20.125.2.50 `bool Mailbox_TimedReceive (Mailbox_t handle, void * pvData_, uint32_t u32TimeoutMS_)`

Mailbox_TimedReceive.

See also

bool [Mailbox::Receive\(void *pvData_, uint32_t u32TimeoutMS_\)](#)

Parameters

<i>handle</i>	Handle of the mailbox object
<i>pvData_</i>	Pointer to a buffer that will have the envelope's contents copied into upon delivery.

<i>u32TimeoutMS_</i>	Maximum time to wait for delivery.
----------------------	------------------------------------

Returns

true - envelope was delivered, false - delivery timed out.

20.125.2.51 `bool Mailbox_TimedReceiveTail (Mailbox_t handle, void * pvData_, uint32_t u32TimeoutMS_)`

Mailbox_TimedReceiveTail.

See also

bool [Mailbox::ReceiveTail\(void *pvData_, uint32_t u32TimeoutMS_\)](#)

Parameters

<i>handle</i>	Handle of the mailbox object
<i>pvData_</i>	Pointer to a buffer that will have the envelope's contents copied into upon delivery.
<i>u32TimeoutMS_</i>	Maximum time to wait for delivery.

Returns

true - envelope was delivered, false - delivery timed out.

20.125.2.52 `bool Mailbox_TimedSend (Mailbox_t handle, void * pvData_, uint32_t u32TimeoutMS_)`

Mailbox_TimedSend.

See also

bool [Mailbox::Send\(void *pvData_, uint32_t u32TimeoutMS_\)](#)

Parameters

<i>handle</i>	Handle of the mailbox object
<i>pvData_</i>	Pointer to the data object to send to the mailbox.
<i>u32TimeoutMS_</i>	Maximum time to wait for a free transmit slot

Returns

true - envelope was delivered, false - mailbox is full.

20.125.2.53 `bool Mailbox_TimedSendTail (Mailbox_t handle, void * pvData_, uint32_t u32TimeoutMS_)`

Mailbox_TimedSendTail.

See also

bool [Mailbox::Send\(void *pvData_, uint32_t u32TimeoutMS_\)](#)

Parameters

<i>handle</i>	Handle of the mailbox object
<i>pvData_</i>	Pointer to the data object to send to the mailbox.
<i>u32TimeoutMS_</i>	Maximum time to wait for a free transmit slot

Returns

true - envelope was delivered, false - mailbox is full.

20.125.2.54 `uint16_t Message_GetCode (Message_t handle)`

Message_GetCode.

See also

`uint16_t Message::GetCode()`

Parameters

<i>handle</i>	Handle of the message object
---------------	------------------------------

Returns

user code set in the object

20.125.2.55 `void* Message_GetData (Message_t handle)`

Message_GetData.

See also

`void* Message::GetData()`

Parameters

<i>handle</i>	Handle of the message object
---------------	------------------------------

Returns

Pointer to the data set in the message object

20.125.2.56 `void Message_Init (Message_t handle)`

Message_Init.

See also

`void Message::Init()`

Parameters

<i>handle</i>	Handle of the message object
---------------	------------------------------

20.125.2.57 void Message_SetCode (Message_t *handle*, uint16_t *u16Code_*)

Message_SetCode.

See also

void [Message::SetCode\(uint16_t u16Code_\)](#)

Parameters

<i>handle</i>	Handle of the message object
<i>u16Code_</i>	Data code to set in the object

20.125.2.58 void Message_SetData (Message_t *handle*, void * *pvData_*)

Message_SetData.

See also

void [Message::SetData\(void *pvData_\)](#)

Parameters

<i>handle</i>	Handle of the message object
<i>pvData_</i>	Pointer to the data object to send in the message

20.125.2.59 uint16_t MessageQueue_GetCount (void)

MessageQueue_GetCount.

See also

uint16_t [MessageQueue::GetCount\(\)](#)

Returns

Count of pending messages in the queue.

20.125.2.60 void MessageQueue_Init (MessageQueue_t *handle*)

MessageQueue_Init.

See also

void [MessageQueue::Init\(\)](#)

Parameters

<i>handle</i>	Handle to the message queue to initialize
---------------	---

20.125.2.61 **Message_t** MessageQueue_Receive (**MessageQueue_t** *handle*)

MessageQueue_Receive.

See also

[Message_t MessageQueue::Receive\(\)](#)

Parameters

<i>handle</i>	Handle of the message queue object
---------------	------------------------------------

Returns

Pointer to a message object at the head of the queue

20.125.2.62 **void** MessageQueue_Send (**MessageQueue_t** *handle*, **Message_t** *hMessage_*)

MessageQueue_Send.

See also

void [MessageQueue::Send\(Message *pclMessage_\)](#)

Parameters

<i>handle</i>	Handle of the message queue object
<i>hMessage_</i>	Handle to the message to send to the given queue

20.125.2.63 **Message_t** MessageQueue_TimedReceive (**MessageQueue_t** *handle*, **uint32_t** *u32TimeWaitMS_*)

MessageQueue_TimedReceive.

See also

[Message_t MessageQueue::TimedReceive\(uint32_t u32TimeWaitMS_\)](#)

Parameters

<i>handle</i>	Handle of the message queue object
<i>u32TimeWaitMS_</i>	The amount of time in ms to wait for a message before timing out and unblocking the waiting thread.

Returns

Pointer to a message object at the head of the queue or NULL on timeout.

20.125.2.64 **void** Mutex_Claim (**Mutex_t** *handle*)

Mutex_Claim.

See also

void [Mutex::Claim\(\)](#)

Parameters

<i>handle</i>	Handle of the mutex
---------------	---------------------

20.125.2.65 `void Mutex_Init (Mutex_t handle)`

Mutex_Init.

See also

`void Mutex::Init\(\)`

Parameters

<i>handle</i>	Handle of the mutex
---------------	---------------------

20.125.2.66 `void Mutex_Release (Mutex_t handle)`

Mutex_Release.

See also

`void Mutex::Release\(\)`

Parameters

<i>handle</i>	Handle of the mutex
---------------	---------------------

20.125.2.67 `bool Mutex_TimedClaim (Mutex_t handle, uint32_t u32WaitTimeMS_)`

Mutex_TimedClaim.

See also

`bool Mutex::Claim\(uint32_t u32WaitTimeMS_\)`

Parameters

<i>handle</i>	Handle of the mutex
<i>u32WaitTimeMS_</i>	Time to wait before aborting

Returns

true if mutex was claimed, false on timeout

20.125.2.68 `void Notify_Init (Notify_t handle)`

Notify_Init.

See also

`void Notify::Init\(\)`

Parameters

<i>handle</i>	Handle of the notification object
---------------	-----------------------------------

20.125.2.69 void Notify_Signal (**Notify_t** *handle*)

Notify_Signal.

See also

void [Notify::Signal\(\)](#)

Parameters

<i>handle</i>	Handle of the notification object
---------------	-----------------------------------

20.125.2.70 bool Notify_TimedWait (**Notify_t** *handle*, uint32_t *u32WaitTimeMS_*, bool * *pbFlag_*)

Notify_TimedWait.

See also

bool [Notify::Wait](#)(uint32_t *u32WaitTimeMS_*, bool **pbFlag_*)

Parameters

<i>handle</i>	Handle of the notification object
<i>u32WaitTimeMS_</i>	Maximum time to wait for notification in ms
<i>pbFlag_</i>	Flag to set to true on notification

Returns

true on unblock, false on timeout

20.125.2.71 void Notify_Wait (**Notify_t** *handle*, bool * *pbFlag_*)

Notify_Wait.

See also

void [Notify::Wait](#)(bool **pbFlag_*)

Parameters

<i>handle</i>	Handle of the notification object
<i>pbFlag_</i>	Flag to set to true on notification

20.125.2.72 void Scheduler_Enable (bool *bEnable_*)

Scheduler_Enable.

See also

void [Scheduler::SetScheduler](#)(bool *bEnable_*)

Parameters

<i>bEnable_true</i>	to enable, false to disable the scheduler
---------------------	---

20.125.2.73 Thread_t Scheduler_GetCurrentThread (void)

Scheduler_GetCurrentThread.

See also

Thread* [Scheduler::GetCurrentThread\(\)](#)

Returns

Handle of the currently-running thread

20.125.2.74 bool Scheduler_IsEnabled (void)

Scheduler_IsEnabled.

See also

bool [Scheduler::IsEnabled\(\)](#)

Returns

true - scheduler enabled, false - disabled

20.125.2.75 void Semaphore_Init (Semaphore_t handle, uint16_t u16InitVal_, uint16_t u16MaxVal_)

Semaphore_Init.

See also

void [Semaphore::Init\(uint16_t u16InitVal_, uint16_t u16MaxVal_\)](#)

Parameters

<i>handle</i>	Handle of the semaphore
<i>u16InitVal_</i>	Initial value of the semaphore
<i>u16MaxVal_</i>	Maximum value that can be held for a semaphore

20.125.2.76 void Semaphore_Pend (Semaphore_t handle)

Semaphore_Pend.

See also

void [Semaphore::Pend\(\)](#)

Parameters

<i>handle</i>	Handle of the semaphore
---------------	-------------------------

20.125.2.77 `void Semaphore_Post (Semaphore_t handle)`

Semaphore_Post.

See also

`void Semaphore::Post()`

Parameters

<i>handle</i>	Handle of the semaphore
---------------	-------------------------

20.125.2.78 `bool Semaphore_TimedPend (Semaphore_t handle, uint32_t u32WaitTimeMS_)`

Semaphore_TimedPend.

See also

`bool Semaphore::Pend(uint32_t u32WaitTimeMS_)`

Parameters

<i>handle</i>	Handle of the semaphore
<i>u32WaitTimeMS_</i>	Time in ms to wait

Returns

true if semaphore was acquired, false on timeout

20.125.2.79 `void Thread_Exit (Thread_t handle)`

Thread_Exit.

See also

`void Thread::Exit()`

Parameters

<i>handle</i>	Handle of the thread
---------------	----------------------

20.125.2.80 `PORT_PRIO_TYPE Thread_GetCurPriority (Thread_t handle)`

Thread_GetCurPriority.

See also

`PORT_PRIO_TYPE Thread::GetCurPriority()`

Parameters

<i>handle</i>	Handle of the thread
---------------	----------------------

Returns

Current priority of the thread considering priority inheritance

20.125.2.81 `uint8_t Thread_GetID (Thread_t handle)`

Thread_GetID.

See also

`uint8_t Thread::GetID()`

Parameters

<i>handle</i>	Handle of the thread
---------------	----------------------

Returns

Return ID assigned to the thread

20.125.2.82 `PORT_PRIO_TYPE Thread_GetPriority (Thread_t handle)`

Thread_GetPriority.

See also

`PORT_PRIO_TYPE Thread::GetPriority()`

Parameters

<i>handle</i>	Handle of the thread
---------------	----------------------

Returns

Current priority of the thread not considering priority inheritance

20.125.2.83 `uint16_t Thread_GetQuantum (Thread_t handle)`

Thread_GetQuantum.

See also

`uint16_t Thread::GetQuantum()`

Parameters

<i>handle</i>	Handle of the thread
---------------	----------------------

Returns

`Thread`'s current execution quantum

20.125.2.84 `uint16_t Thread_GetStackSlack (Thread_t handle)`

`Thread_GetStackSlack`.

See also

`uint16_t Thread::GetStackSlack()`

Parameters

<i>handle</i>	Handle of the thread
---------------	----------------------

Returns

Return the amount of unused stack on the given thread

20.125.2.85 `ThreadState_t Thread_GetState (Thread_t handle)`

`Thread_GetState`.

See also

`ThreadState_t Thread::GetState()`

Parameters

<i>handle</i>	Handle of the thread
---------------	----------------------

Returns

The thread's current execution state

20.125.2.86 `void Thread_Init (Thread_t handle, K_WORD * pwStack_, uint16_t u16StackSize_, PORT_PRIO_TYPE uXPriority_, ThreadEntry_t pfEntryPoint_, void * pvArg_)`

`Thread_Init`.

See also

`void Thread::Init(K_WORD *pwStack_, uint16_t u16StackSize_, PORT_PRIO_TYPE uXPriority_, ThreadEntry_t pfEntryPoint_, void *pvArg_)`

Parameters

<i>handle</i>	Handle of the thread to initialize
<i>pwStack_</i>	Pointer to the stack to use for the thread
<i>u16StackSize_</i>	Size of the stack (in bytes)
<i>uXPriority_</i>	Priority of the thread (0 = idle, 7 = max)
<i>pfEntryPoint_</i>	This is the function that gets called when the thread is started
<i>pvArg_</i>	Pointer to the argument passed into the thread's entryptoint function.

20.125.2.87 `void Thread_SetID (Thread_t handle, uint8_t u8ID_)`

`Thread_SetID`.

See also

`void Thread::SetID(uint8_t u8ID_)`

Parameters

<i>handle</i>	Handle of the thread
<i>u8ID_</i>	ID To assign to the thread

20.125.2.88 void Thread_SetPriority (Thread_t *handle*, PORT_PRIO_TYPE *uXPriority_*)

Thread_SetPriority.

See also

void [Thread::SetPriority\(PORT_PRIO_TYPE uXPriority_\)](#)

Parameters

<i>handle</i>	Handle of the thread
<i>uXPriority_</i>	New priority level

20.125.2.89 void Thread_SetQuantum (Thread_t *handle*, uint16_t *u16Quantum_*)

Thread_SetQuantum.

See also

void [Thread::SetQuantum\(uint16_t u16Quantum_\)](#)

Parameters

<i>handle</i>	Handle of the thread
<i>u16Quantum_</i>	Time (in ticks) to set for the thread execution quantum

20.125.2.90 void Thread_Sleep (uint32_t *u32TimeMs_*)

Thread_Sleep.

See also

void [Thread::Sleep\(uint32_t u32TimeMs_\)](#)

Parameters

<i>u32TimeMs_</i>	Time in ms to block the thread for
-------------------	------------------------------------

20.125.2.91 void Thread_Start (Thread_t *handle*)

Thread_Start.

See also

void [Thread::Start\(\)](#)

Parameters

<i>handle</i>	Handle of the thread to start
---------------	-------------------------------

20.125.2.92 `void Thread_Stop (Thread_t handle)`

Thread_Stop.

See also

`void Thread::Stop()`

Parameters

<i>handle</i>	Handle of the thread to stop
---------------	------------------------------

20.125.2.93 `void Thread_USleep (uint32_t u32TimeUs_)`

Thread_USleep.

See also

`void Thread::USleep(uint32_t u32TimeUs_)`

Parameters

<i>u32TimeUs_</i>	Time in us to block the thread for
-------------------	------------------------------------

20.125.2.94 `void Thread_Yield (void)`

Thread_Yield.

See also

`void Thread::Yield()`

20.125.2.95 `void Timer_Init (Timer_t handle)`

Timer_Init.

See also

`void Timer::Init()`

Parameters

<i>handle</i>	Handle of the timer
---------------	---------------------

20.125.2.96 `void Timer_Restart (Timer_t handle)`

Timer_Restart.

See also

`void Timer::Start()`

Parameters

<i>handler</i>	Handle of the timer to restart.
----------------	---------------------------------

20.125.2.97 void Timer_Start (Timer_t *handle*, bool *bRepeat*_, uint32_t *u32IntervalMs*_, uint32_t *u32ToleranceMs*_, TimerCallbackC_t *pfCallback*_, void * *pvData*_)

Timer_Start.

See also

void [Timer::Start](#)(bool *bRepeat*_, uint32_t *u32IntervalMs*_, uint32_t *u32ToleranceMs*_, TimerCallbackC_t *pfCallback*_, void * *pvData*_)↵

Parameters

<i>handle</i>	Handle of the timer
<i>bRepeat</i> _	Restart the timer continuously on expiry
<i>u32IntervalMs</i> ↵ _	Time in ms to expiry
<i>u32ToleranceMs</i> ↵ _	Group with other timers if they expire within the amount of time specified
<i>pfCallback</i> _	Callback to run on timer expiry
<i>pvData</i> _	Data to pass to the callback on expiry

20.125.2.98 void Timer_Stop (Timer_t *handle*)

Timer_Stop.

See also

void [Timer::Stop](#)()

Parameters

<i>handle</i>	Handle of the timer
---------------	---------------------

Lab Example 10: Thread Notifications

Lessons covered in this example include:
- Create a notification object, and use it to synchronize execution of Threads.

Takeaway:
- Notification objects are a lightweight mechanism to signal thread execution
  in situations where even a semaphore would be a heavier-weight option.

=====*/
#if !KERNEL_USE_IDLE_FUNC
#error "This demo requires KERNEL_USE_IDLE_FUNC"
#endif

extern "C" {
void __cxa_pure_virtual(void)
{
}
}

//-----
#define APP_STACK_SIZE (256 / sizeof(K_WORD))
static Thread clApp1Thread;
static K_WORD awApp1Stack[APP_STACK_SIZE];
static void App1Main(void* unused_);

//-----
static Thread clApp2Thread;

```

Takeaway:

- Mailboxes are a powerful IPC mechanism used to pass messages of a fixed-size between threads.

}

```

```
//-----
int main(void)
{
    // Before any Mark3 RTOS APIs can be called, the user must call Kernel::Init().
    // Note that if you have any hardware-specific init code, it can be called
    // before Kernel::Init, so long as it does not enable interrupts, or
    // rely on hardware peripherals (timer, software interrupt, etc.) used by the
    // kernel.
    Kernel::Init();

    // Once the kernel initialization has been complete, the user can add their
    // application thread(s) and idle thread. Threads added before the kernel
    // is started are referred to as the "static threads" in the system, as they
    // are the default working-set of threads that make up the application on
    // kernel startup.

    // Initialize the application thread to use a specified word-array as its stack.
    // The thread will run at priority level "1", and start execution the
    // "AppMain" function when it's started.
    clAppThread.Init(awAppStack, sizeof(awAppStack), 1, AppMain, 0);

    // Initialize the idle thread to use a specific word-array as its stack.
    // The thread will run at priority level "0", which is reserved for the idle
    // priority thread. IdleMain will be run when the thread is started.
    clIdleThread.Init(awIdleStack, sizeof(awIdleStack), 0, IdleMain, 0);

    // Once the static threads have been added, the user must then ensure that the
    // threads are ready to execute. By default, creating a thread is created
    // in a STOPPED state. All threads must manually be started using the
    // Start() API before they will be scheduled by the system. Here, we are
    // starting the application and idle threads before starting the kernel - and
    // that's OK. When the kernel is started, it will choose which thread to run
    // first from the pool of ready threads.

    clAppThread.Start();
    clIdleThread.Start();

    // All threads have been initialized and made ready. The kernel will now
    // select the first thread to run, enable the hardware required to run the
    // kernel (Timers, software interrupts, etc.), and then do whatever is
    // necessary to maneuver control of thread execution to the kernel. At this
    // point, execution will transition to the highest-priority ready thread.
    // This function will not return.

    Kernel::Start();

    // As Kernel::Start() results in the operating system being executed, control
    // will not be relinquished back to main(). The "return 0" is simply to
    // avoid warnings.

    return 0;
}

//-----
void AppMain(void* unused_)
{
    // This function is run from within the application thread. Here, we
    // simply print a friendly greeting and allow the thread to sleep for a
    // while before repeating the message. Note that while the thread is
    // sleeping, CPU execution will transition to the Idle thread.

    while (1) {
        KernelAware::Print("Hello World!\n");
        Thread::Sleep(1000);

}

//-----
void IdleMain(void)
{
    // Low priority task + power management routines go here.
    // The actions taken in this context must *not* cause a blocking call,
    // similar to the requirements for an idle thread.

    // Note that unlike an idle thread, the idle function must run to
    // completion. As this is also called from a nested interrupt context,
    // it's worthwhile keeping this function brief, limited to absolutely
    // necessary functionality, and with minimal stack use.
}
```

21.6 lab3_round_robin/main.cpp

This example demonstrates how to use round-robin thread scheduling with multiple threads of the same priority.

[illegible]

```

#define APP1_STACK_SIZE (320 / sizeof(K_WORD))
static Thread clApp1Thread;
static K_WORD awApp1Stack[APP1_STACK_SIZE];
static void App1Main(void* unused_);

//-----
// This block declares the thread data for one main application thread. It
// defines a thread object, stack (in word-array form), and the entry-point
// function used by the application thread.
#define APP2_STACK_SIZE (320 / sizeof(K_WORD))
static Thread clApp2Thread;
static K_WORD awApp2Stack[APP2_STACK_SIZE];
static void App2Main(void* unused_);

//-----
int main(void)
{
    // See the annotations in lab1.
    Kernel::Init();

    // In this exercise, we create two threads at the same priority level.
    // As a result, the CPU will automatically swap between these threads
    // at runtime to ensure that each get a chance to execute.

    clApp1Thread.Init(awApp1Stack, sizeof(awApp1Stack), 1, App1Main, 0);
    clApp2Thread.Init(awApp2Stack, sizeof(awApp2Stack), 1, App2Main, 0);

    // Set the threads up so that Thread 1 can get 4ms of CPU time uninterrupted,
    // but Thread 2 can get 8ms of CPU time uninterrupted. This means that
    // in an ideal situation, Thread 2 will get to do twice as much work as
    // Thread 1 - even though they share the same scheduling priority.

    // Note that if SetQuantum() isn't called on a thread, a default value
    // is set such that each thread gets equal timeslicing in the same
    // priority group by default. You can play around with these values and
    // observe how it affects the execution of both threads.

    clApp1Thread.SetQuantum(4);
    clApp2Thread.SetQuantum(8);

    clApp1Thread.Start();
    clApp2Thread.Start();

    Kernel::Start();

    return 0;
}

//-----
void App1Main(void* unused_)
{
    // Simple loop that increments a volatile counter to 1000000 then resets
    // it while printing a message.
    volatile uint32_t u32Counter = 0;
    while (1) {
        u32Counter++;
        if (u32Counter == 1000000) {
            u32Counter = 0;
            KernelAware::Print("Thread 1 - Did some work\n");
        }
    }
}

//-----
void App2Main(void* unused_)
{
    // Same as App1Main. However, as this thread gets twice as much CPU time
    // as Thread 1, you should see its message printed twice as often as the
    // above function.
    volatile uint32_t u32Counter = 0;
    while (1) {
        u32Counter++;
        if (u32Counter == 1000000) {
            u32Counter = 0;
            KernelAware::Print("Thread 2 - Did some work\n");
        }
    }
}

```

21.7 lab4_semaphores/main.cpp

This example demonstrates how to use semaphores for [Thread](#) synchronization.

[illegible]

```

void __cxa_pure_virtual(void)
{
}

//-----
// This block declares the thread data for one main application thread. It
// defines a thread object, stack (in word-array form), and the entry-point
// function used by the application thread.
#define APP1_STACK_SIZE (320 / sizeof(K_WORD))

{
    while (1) {
        // Claim the mutex. This will prevent any other thread from claiming
        // this lock simulatenously. As a result, the other thread has to
        // wait until we're done before it can do its work. You will notice
        // that the Start/Done prints for the thread will come as a pair (i.e.
        // you won't see "Thread2: Start" then "Thread1: Start").

        clMyMutex.Claim();

        // Start our work (incrementing a counter). Notice that the Start and
        // Done prints wind up as a pair when simulated with flAVR.

        KernelAware::Print("Thread1: Start\n");
        u32Counter++;
        while (u32Counter <= 1000000) {
            u32Counter++;
        }
        u32Counter = 0;
        KernelAware::Print("Thread1: Done\n");

        // Release the lock, allowing the other thread to do its thing.
        clMyMutex.Release();
    }
}

//-----
void App2Main(void* unused_)
{
    while (1) {
        // Claim the mutex. This will prevent any other thread from claiming
        // this lock simulatenously. As a result, the other thread has to

```

```

Kernel::Start();

return 0;
}

//-----
void PeriodicCallback(Thread* owner, void* pvData_)
{
    // Timer callback function used to post a semaphore. Posting the semaphore
    // will wake up a thread that's pending on that semaphore.
    Semaphore* pclSem = (Semaphore*)pvData_;
    pclSem->Post();
}

//-----
void OneShotCallback(Thread* owner, void* pvData_)
{
    KernelAware::Print("One-shot timer expired.\n");
}

//-----
void ApplMain(void* unused_)
{
    Timer clMyTimer; // Periodic timer object
    Timer clOneShot; // One-shot timer object

    Semaphore clMySem; // Semaphore used to wake this thread

    // Initialize a binary semaphore (maximum value of one, initial value of
    // zero).
    clMySem.Init(0, 1);

    // Start a timer that triggers every 500ms that will call PeriodicCallback.
    // This timer simulates an external stimulus or event that would require
    // an action to be taken by this thread, but would be serviced by an
    // interrupt or other high-priority context.

    // PeriodicCallback will post the semaphore which wakes the thread
    // up to perform an action. Here that action consists of a trivial message
    // print.
    clMyTimer.Start(true, 500, PeriodicCallback, (void*)&clMySem);

    // Set up a one-shot timer to print a message after 2.5 seconds, asynchronously
    // from the execution of this thread.
    clOneShot.Start(false, 2500, OneShotCallback, 0);

    while (1) {
        // Wait until the semaphore is posted from the timer expiry
        clMySem.Pend();

        // Take some action after the timer posts the semaphore to wake this
        // thread.
        KernelAware::Print("Thread Triggered.\n");
    }
}

```

21.10 lab7_events/main.cpp

This example demonstrates how to create and use event groups

[illegible]

-Explore the behavior of the EVENT_FLAG_ANY and EVENT_FLAG_ALL, and the event-mask bitfield.

Takeaway:

Like Semaphores and Mutexes, EventFlag objects can be used to synchronize the execution of threads in a system. The EventFlag class allows for many threads to share the same object, blocking on different event combinations. This provides an efficient, robust way for threads to process asynchronous system events that occur with a unified interface.

```

```

21.11 lab8_messages/main.cpp

This example demonstrates how to pass data between threads using message passing.

[illegible]

"data" members. This mechanism can be used to pass data between threads extremely efficiently, with a simple and flexible API. Any number of threads can write to/block on a single message queue, which give this method of IPC even more flexibility.

```
